SUBJECT: COMANCHE PEAK NUCLEAR POWER PLANT, UNITS 1 AND 2
DOCKET NUMBERS 50-445 AND 50-446
FACILITY OPERATING LICENSE NUMBERS NPF-87 and NPF-89
LICENSE RENEWAL APPLICATION

REFERENCE: Letter TXX-20077 dated August 31, 2020, from Steven K. Sewell to the NRC, submitting Comanche Peak Nuclear Power Plant License Renewal Application Submittal Schedule Revision (ADAMS Accession No. ML20244A274)

Dear Sir or Madam:

Pursuant to 10 CFR Part 54, Vistra Operations Company LLC ("Vistra OpCo") submits an operating license renewal application (LRA) for Comanche Peak Nuclear Power Plant (CPNPP) Units 1 and 2 to extend the current operating licenses an additional 20 years beyond their current expiration dates. With renewal, the following would ensue:

- CPNPP Unit 1 (NPF-87) operating license would be extended from midnight on February 8, 2030, to midnight on February 8, 2050 and
- CPNPP Unit 2 (NPF-89) operating license would be extended from midnight on February 2, 2033, to midnight on February 2, 2053.

Vistra OpCo also requests renewal of the source, special nuclear material, and by-product licenses under 10 CFR Parts 30, 40, and 70 that are subsumed in or combined with the current operating licenses.

The LRA contains the information required by 10 CFR Part 54 for the contents of the application. The application contains technical information required by 10 CFR 54.21 and includes an environmental report prepared in accordance with 10 CFR 54.23 and Subpart A of 10 CFR 51.

In accordance with 10 CFR 54.21(b), each year following submittal of the LRA and at least 3 months before the scheduled completion of the staff's review, VistraOpCo will submit an LRA amendment identifying any current licensing basis changes that materially affect the contents of the LRA, including the FSAR supplement.

CPNPP LRA Appendix A, Section A.4, "License Renewal Commitments List", provides a summary of the commitments made in the application. This summary will be updated as required throughout the LRA review process.

In accordance with 10 CFR 50.91, a copy of this application is being provided to the designated Texas State Official.

Direct any questions regarding this submittal to Todd Evans at (254) 897-8987 or Todd.Evans@Luminant.com.

I state under penalty of perjury that the foregoing is true and correct.

Executed on October 3, 2022

Sincerely,

Steven K. Sewell

1.0. ADMINISTRATIVE INFORMATION

Pursuant to Title 10, Part 54, of the "Code of Federal Regulations (10 CFR Part 54), Requirements for Renewal of Operating Licenses for Nuclear Power Plants" (Reference 1.7.1), this license renewal application (LRA) seeks renewal for an additional 20-year term of the facility operating licenses for Comanche Peak Nuclear Power Plant (CPNPP) Unit 1 (NPF-87) (Reference 1.7.2) and Unit 2 (NPF-89) (Reference 1.7.3). The LRA includes renewal of the source, special nuclear, and byproduct materials licenses that are combined in the Unit 1 and Unit 2 licenses.

The LRA is based on the guidance provided by the U.S Nuclear Regulatory Commission (NRC) in Nuclear Regulatory Commission Regulation (NUREG)-1800, Revision 2, "Standard Review Plan for Review of License Renewal Applications for Nuclear Power Plants" (Reference 1.7.4), Regulatory Guide (RG) 1.188, Revision 2, "Standard Format and Content for Applications to Renew Nuclear Power Plant Operating Licenses" (Reference 1.7.5), and the guidance provided by Nuclear Energy Institute (NEI) in NEI 95-10, Revision 6, "Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule" (Reference 1.7.6).

The LRA is intended to provide sufficient information for the NRC to complete its technical and environmental reviews pursuant to 10 CFR Part 54, "Requirements for Renewal of Operating Licenses for Nuclear Power Plants," and 10 CFR Part 51, "Environmental Protection Regulations for Domestic Licensing and Related Regulatory Functions" (Reference 1.7.7). The LRA is provided to meet the standards required by 10 CFR 54.29 in support of the issuance of the renewed operating licenses for CPNPP Units 1 and 2.

1.1. GENERAL INFORMATION – 10 CFR 54.17 and 10 CFR 54.19

The following is general information required by 10 CFR 54.17 and 10 CFR 54.19.

1.1.1. Name of Applicant

Vistra Operations Company LLC (Vistra OpCo) (operator) is acting on its own behalf and for Comanche Peak Power Company LLC (CP PowerCo) (owner) by submitting this application. Vistra OpCo hereby applies for renewed operating licenses for CPNPP Units 1 and 2.

1.1.2. Address of Applicant

Vistra Operations Company LLC (operator)
P O Box 1002
Glen Rose, TX 76043

Comanche Peak Power Company LLC (owner)
P O Box 1002
Glen Rose, TX 76043

1.1.3. Description of Business or Occupation of Applicant

Vistra OpCo (operator) is acting on its own behalf and for Comanche Peak Power Company LLC ("CP PowerCo") (owner) by submitting this application. Vistra OpCo is a Delaware limited liability company, which in turn is wholly owned by Vistra Intermediate Company LLC, a Delaware limited liability company, which in turn is wholly owned by Vistra Corp. (Vistra), a corporation formed under the laws of the State of Delaware with principal executive offices in Irving, TX. Vistra OpCo is the current licensed operator of CPNPP Units 1 and 2, which are the subject of the LRA. The current operating licenses will expire as follows:

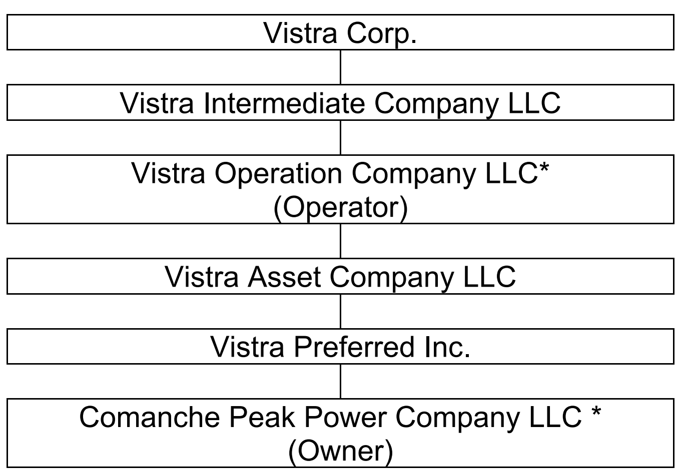
- At midnight on February 8, 2030 for Unit 1 (Facility Operating License (FOL) No. NPF-87)
- At midnight on February 2, 2033 for Unit 2 (FOL No. NPF-89)

Vistra OpCo will continue as the licensed operator for the renewed operating licenses and CP PowerCo will continue as the owner.

1.1.4. Organization and Management of Applicant

CP PowerCo is not owned, controlled, or dominated by an alien, a foreign corporation, or a foreign government. All executive personnel, directors, and managers of Vistra OpCo and CP PowerCo are citizens of the United States. A simplified Corporate / Licensee organization diagram and the names and business addresses of Vistra OpCo and CP PowerCo executive personnel, directors, and managers are provided below (including their respective ultimate parent and intermediate parents).

Corporate / Licensee(s)
(Simplified Organization Diagram)



* Denotes NRC Licensee

Condition 3 of NRC Order dated May 6, 2016, (Reference 1.7.8) (approving transfer of licenses and conforming amendments) stated "The Reorganized TCEH (Vistra Corp) Board of Directors shall adopt resolutions that any non-U.S. citizens or foreign-appointed U.S. citizens serving as either directors or executive officers of Reorganized TCEH (Vistra Corp), the ultimate parent, and intermediate parents of CP LLC (CP PowerCo) and OpCo LLC (Vistra OpCo) shall not seek access to any classified information or to special nuclear material in the custody of the CPNPP licensees and shall not participate in or seek to influence operational decisions by the licensees regarding nuclear safety or security matters."

TXX-16108 dated October 13, 2016, (Reference 1.7.9) notified the NRC that at the first meeting of TCEH Corp. (Vistra Corp), Board of Directors, the Board adopted resolutions in compliance with Condition 3 of NRC Order dated May 6, 2016.

On November 14, 2016, TEX Operations Company LLC changed the company name of "TEX Operations Company LLC" to "Vistra Operations Company LLC". This was done as part of a companywide "re-branding" effort by Vistra Energy Corp. (the ultimate parent) to conform with the Vistra brand. The NRC-approved the administrative name change to Vistra Operations Company LLC in license amendment 169 (Reference ML17129A024).

The rebranding effort in the fall of 2016 also changed the names of the ultimate parent and intermediate parent(s) as reflected in the simplified organizational chart above. In July 2020, as part of a corporate re-branding, "Vistra Energy Corp." was changed to "Vistra Corp." This was an editorial change only and had no impact to CPNPP and was reflected in an update to Figure 13.1-1 of Certified Final Safety Analysis Report (FSAR) Amendment 110 (References ML20226A417 and ML20315A098).

The names and business addresses of Vistra Corp., Vistra Intermediate Company LLC, Vistra Operations Company LLC, Vistra Asset Company LLC, Vistra Preferred Inc., and CP PowerCo directors and officers are provided below:

Tom McCool	Site Vice-President*	6555 Sierra Drive Irving, TX 75039

* “Dual-hatted” personnel (as officers and/or senior manager of Vistra OpCo and Luminant Generation Company LLC (”Luminant”) as described by letters TXX-16109 dated September 16, 2016 (Reference 1.7.10) and TXX-16108 dated October 13, 2016.

1.1.5. <u>Class of License, Use of the Facility, and the Period of Time for which the License is Sought</u>

Vistra OpCo requests renewal of the Class 103 operating licenses for CPNPP Units 1 and 2 for a period of 20 years beyond the expiration of the current licenses to allow continued use of the facilities for the commercial generation of electricity. CPNPP Unit 1 license (NPF-87) expires at midnight on February 8, 2030, and the Unit 2 license (NPF-89) expires at midnight on February 2, 2033. Extension of the renewed licenses would cause NPF-87 to expire at midnight on February 8, 2050, and NPF-89 to expire at midnight on February 2, 2053.

In this LRA, Vistra OpCo also requests renewal of the source, special nuclear material, and by-product licenses under 10 CFR Parts 30, 40, and 70 that are subsumed in or combined with the current operating licenses.

1.1.6. Earliest and Latest Dates for Alterations, If Proposed

No physical plant alterations or modifications have been identified as necessary in order to implement the provisions of the LRA. The current licensing basis (CLB) will be continued and maintained throughout the period of extended operation (PEO).

1.1.7. Listing of Regulatory Agencies Having Jurisdiction and News Publications

Regulatory Agencies

Electric Reliability Council of Texas
7620 Metro Center Drive
Austin, TX 78744

Public Utility Commission of Texas
1701 N. Congress Avenue
PO Box 13326
Austin, TX 78711-3326

Local News Publications

News publications which circulate in the area surrounding CPNPP Units 1 and 2 that are considered appropriate to give reasonable notice of the LRA to those municipalities, private utilities, public bodies, and cooperatives that might have a potential interest are as follows:

Hood County News
1501 S. Morgan
PO Box 879
Granbury, TX 76048

Glen Rose Reporter
PO Box 2009
Glen Rose, TX 76043

1.1.8. Conforming Changes to Standard Indemnity Agreement

10 CFR 54.19(b) requires that LRAs include “conforming changes to the standard indemnity agreement, 10 CFR 140.92, Appendix B, to account for the expiration term of the proposed renewed license.” The current Indemnity Agreement B-96 for CPNPP state in Article VII that the Agreement shall terminate at the time of expiration of the license specified in Item 3 of the Attachment (to the Agreement). Item 3 of the Attachment to the Indemnity Agreement, as revised through Amendment No. 14 (References ML17129A024 and ML17276A337), lists CPNPP

operating license numbers NPF-87 and NPF-89. Vistra OpCo has reviewed the original Indemnity Agreement and the Amendments. Neither Article VII nor Item 3 of the Attachment specifies an expiration date for operating license numbers NPF-87 and NPF-89. Therefore, no changes to the Indemnity Agreement are deemed necessary as part of this application. Should the license numbers be changed by NRC upon issuance of the renewed licenses, Vistra OpCo requests that NRC amend the Indemnity Agreement to include conforming changes to Item 3 of the Attachment and other affected sections of the Agreement.

1.1.9. Restricted Data

With regard to the requirements of 10 CFR 54.17(f), this LRA does not contain any "Restricted Data," as that term is defined in the Atomic Energy Act of 1954, as amended, or other defense information, and it is not expected that any such information will become involved in these licensed activities.

In accordance with the requirements of 10 CFR 54.17(g), Vistra OpCo will not permit any individual to have access to, or any facility to possess Restricted Data or classified National Security Information until the individual and/or facility has been approved for such access under the provisions of 10 CFR Parts 25 and/or 95.

See Section 1.1.4 for resolutions regarding directors, managers or executive officers of the ultimate parent and intermediate parents of CP PowerCo and Vistra OpCo.

1.2. GENERAL LICENSE INFORMATION

1.2.1. Application Updates, Renewed Licenses, and Renewal Term Operation

In accordance with 10 CFR 54.21(b), during NRC review of the LRA, an annual update to the application to reflect any change to the CLB that materially affects the content of the LRA will be provided.

In accordance with 10 CFR 54.21(d), Vistra OpCo will maintain a summary list in the Final Safety Analysis Report (FSAR) of activities that are required to manage the effects of aging for the systems, structures, or components within the scope of LR during the PEO and summaries of the time-limited aging analyses evaluations.

1.2.2. Incorporation by Reference

There are no documents incorporated by reference as part of the application. Any document references, either in text or in Section 1.7 are listed for information only.

1.2.3. Contact Information

Any notices, questions, or correspondence in connection with this filing should be directed to:

1.3. PURPOSE

This document provides information required by 10 CFR Part 54 to support the LRA for renewal of the operating licenses. The LRA contains technical information required by 10 CFR 54.21 and environmental information required by 10 CFR 54.23. The information contained herein is intended to provide the NRC with an adequate basis to make the findings required by 10 CFR 54.29.

1.4. DESCRIPTION OF THE PLANT

CPNPP is located on the Squaw Creek Reservoir (SCR) in Somervell County, Texas about 4.5 miles north-northwest of Glen Rose, Texas, and approximately 65 miles southwest of Dallas-Fort Worth in north-central Texas. The site area is approximately 7,700 acres, and the Exclusion Area is approximately 4,170 acres. In addition to the two CPNPP reactors, the site includes the SCR and dam; the SCR, built for station cooling, extends northward into Hood County. Each unit includes a four-loop, pressurized light-water reactor (LWR) Nuclear Steam Supply System (NSSS) supplied by Westinghouse Electric Corporation and associated equipment.

Commercial operation began for CPNPP Unit 1 on August 13, 1990 and began for Unit 2 on August 3, 1993. Each reactor was initially operated at a rated thermal power of 3411 Megawatt thermal (MWt). In 1999, Unit 2 was uprated to 3445 MWt (an increase of 1.0 percent) through the use of use of leading edge flow-meter (LEFM) technology (Reference 1.7.11). In 2001, both units were uprated to 3458 MWt (1.4 percent for Unit 1 and an additional 0.4 percent for Unit 2) using LEFM technology (Reference 1.7.12). In 2008, both units were uprated to 3612 MWt as a result of a Stretch Power Uprate (SPU), which was a 4.5 percent increase from the previous uprate (Reference 1.7.13). The 2008 SPU implemented or took credit for several modifications: setpoint changes for several systems and components, replacement of the Units 1 and 2 high-pressure turbines in order to pass the additional volumetric steam flow, replacement of the heater drain pump third-stage impellers and heater drain pump motors, re-rating of the main generators from 1350 to 1410 megavolt amperes, replacement of the hydrogen and exciter air coolers, replacement of the isophase bus duct coolers, replacement of the main transformers, and nine Unit 1 pipe support modifications.

CPNPP also operates an independent spent fuel storage installation (ISFSI) at the site. The ISFSI is operated under a general license issued pursuant to the provisions of 10 CFR Part 72 (Reference 1.7.14). Therefore, the ISFSI is not in scope for LR.

1.5. APPLICATION STRUCTURE

This LRA is structured in accordance with RG 1.188, "Standard Format and Content for Applications to Renew Nuclear Plant Operating Licenses," and NEI 95-10, "Industry Guideline for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule". NUREG-1800 references NUREG-1801, Revision 2, "Generic Aging Lessons Learned (GALL) Report" (Reference 1.7.15), which was used to determine the adequacy of existing and new aging management programs (AMPs) and which existing programs should be augmented for LR. The results of the aging management review (AMR), using NUREG-1801, have been documented and are illustrated in table format in Section 3, "Aging Management Review Results" of this application.

The application is divided into the following major sections:

Section 1 – Administrative Information

This section provides the administrative information required by 10 CFR 54.17 and 10 CFR 54.19. It describes the plant and states the purpose for this application. Included in this section are the names, addresses, business descriptions, and organization and management descriptions of the applicant, as well as other administrative information. This section also provides an overview of the structure of the application, general references, and a listing of acronyms used throughout the application.

Section 2 – Structures and Components Subject to Aging Management Review

This section describes and justifies the methods used in the integrated plant assessment (IPA) to identify those structures and components subject to an AMR in accordance with the requirements of 10 CFR 54.21(a)(2). These methods consist of 1) scoping, which identifies the systems, structures, and components (SSCs) that are within the scope of 10 CFR 54.4(a) and 2) screening under 10 CFR 54.21(a)(1), which identifies those in-scope structures and components that perform their intended function without moving parts or a change in configuration or properties, and that are not subject to replacement based on a qualified life or specified time period.

Additionally, the results for systems and structures are described in this section. Scoping results are presented in Section 2.2, "Plant Level Scoping Results." Screening results are presented in Sections 2.3, 2.4, and 2.5.

The screening results consist of lists of components or component groups and structures that require an AMR. Brief descriptions of mechanical systems and structures within the scope of LR are provided as background information. Mechanical system and structure intended functions are provided for in-scope systems and structures. For each in-scope system and structure, components requiring an AMR are identified, associated component intended functions are identified, and appropriate reference to the Section 3 Table providing the AMR results is made.

Selected components, such as equipment supports, structural items (e.g., penetration seals, structural bolting, insulation), and passive electrical components, were more effectively scoped and screened as commodities. Under the commodity approach, these component groups were evaluated based upon common environments and materials. Commodities requiring an AMR are presented in Sections 2.4 and 2.5. Component intended functions and references to the applicable Section 3 Table are provided. Component intended functions are also tabulated in Sections 2.3, 2.4 and 2.5 and listed in the AMR Tables in Sections 3.1.2, 3.2.2, 3.3.2, 3.4.2, 3.5.2, and 3.6.2.

Section 3 – Aging Management Review Results

10 CFR 54.21 (a)(3) requires a demonstration that the effects of aging will be adequately managed so that the intended functions will be maintained consistent with the CLB throughout the PEO. Section 3 presents the results of the AMRs. Section 3 is the link between the scoping and screening results provided in Section 2 and the AMPs provided in Appendix B.

AMR results are presented in tabular form, in a format in accordance with NUREG-1800, "Standard Review Plan for Review of License Renewal Applications." For mechanical systems, AMR results are provided in Sections 3.1 through 3.4 for the Reactor Vessel, Reactor Vessel Internals, and Reactor Coolant System, Engineered Safety Features, Auxiliary Systems, and Steam and Power Conversion Systems, respectively. AMR results for Structures and Component Supports are provided in Section 3.5. AMR results for Electrical Commodities are provided in Section 3.6.

Tables are provided in each of these sections in accordance with NUREG-1800, which provide AMR results for components, materials, environments, and aging effects which are addressed in NUREG-1801, and information regarding the degree to which the proposed AMPs are consistent with those recommended in NUREG-1801.

Section 4 – Time-Limited Aging Analyses

Time-limited aging analyses (TLAAs), as defined by 10 CFR 54.3, are listed in this section. This section includes each of the TLAAs identified in NUREG-1800 and in plant-specific analyses. This section includes a summary of the time-dependent aspects of the analyses. A demonstration is provided to show that the analyses remain valid for the PEO, the analyses have been projected to the end of the PEO, or that the effects of aging on the intended function(s) will be adequately managed for the PEO, consistent with 10 CFR 54.21(c)(1)(i) -(iii).

Appendix A –Final Safety Analysis Report Supplement

As required by 10 CFR 54.21(d), the FSAR supplement contains a summary of activities credited for managing the effects of aging for the PEO. In addition, summary descriptions of time-limited aging analyses evaluations are provided. Table 3.0-1, "FSAR Supplement for Aging Management of Applicable Systems," from Revision 2 of NUREG-1800 was used as guidance for the content of the applicable AMP summaries.

Appendix B – Aging Management Programs

Appendix B describes the programs and activities that are credited for managing aging effects for components or structures during the PEO based upon the AMR results provided in Section 3 and the time-limited aging analyses results provided in Section 4.

Sections B.2.2 and B.2.3 discuss those programs that are contained in Chapter X and Chapter XI, respectively, of NUREG-1801. A description of the AMP is provided, and a conclusion based upon the results of an evaluation against each of the ten elements provided in NUREG-1801 is drawn. In some cases, exceptions, and justifications for managing aging, are provided for specific NUREG-1801 elements. Additionally, operating experience (OE) related to the AMP is provided.

Appendix C – Additional Plant-Specific Information (Optional)

This is an optional Appendix for the LRA; for CPNPP this Appendix is not used.

Appendix D – Technical Specification Changes

This Appendix satisfies the requirement in 10 CFR 54.22 to identify technical specification (TS) changes or additions necessary to manage the effects of aging during the PEO. There were no TS Changes identified necessary to manage the effects of aging during the PEO.

Appendix E – Environmental Information

This Appendix satisfies the requirements of 10 CFR 54.23 to provide a supplement to the environmental report that complies with the requirements of subpart A of 10 CFR 51 for CPNPP Units 1 and 2. A separate environmental report supplement is provided for the site.

1.6. ACRONYMS

Table 1.6-1: Acronyms

Acronyms	Meaning
1/4T	Quarter Thickness
3/4T	Three-Quarter Thickness
ΔRT_{NDT}	Increase in Reference Temperature – Nil Ductility Transition (RT_{NDT})
AB	Auxiliary Building
AC	Alternating Current
ACI	American Concrete Institute
ADAMS	Agencywide Documents Access and Management System
AERM	Aging Effect Requiring Management
AFWS	Auxiliary Feedwater System
AISC	American Institute of Steel Construction
ALE	Adverse Localized Environment
AMP	Aging Management Program
AMR	Aging Management Review
AMSAC	ATWS Mitigation Actuation Circuitry
ANSI	American National Standards Institute
AOP	Abnormal Operating Procedure
AOR	Analysis of Record
ARC	Alternate Repair Criteria
ART	Adjusted Reference Temperature
ASCE	American Society of Civil Engineers
ASME	American Society of Mechanical Engineers

Table 1.6-1: Acronyms

Acronyms	Meaning
ASR	Alkali-Silica Reaction
ASTM	American Society for Testing and Materials
ATWS	Anticipated Transient Without Scram
AVB	Antivibration Bar
A600TT	Thermally Treated Alloy 600
A690TT	Thermally Treated Alloy 690
B&PV	Boiler And Pressure Vessel
BAC	Boric Acid Corrosion
BEA	Break Exclusion Area
BIT	Boron Injection Tank
BMI	Bottom-Mounted Instrumentation
BRS	Boron Recycle System
BTP	Branch Technical Position
BTRS	Boron Thermal Regeneration System
BWR	Boiling Water Reactor
CA	Service Air System
CAP	Corrective Action Program
CAS	Compressed Air System
CASS	Cast Austenitic Stainless Steel
CAT	Chemical Additive Tank
CC	Concrete Components
CCP	Centrifugal Charging Pump

Table 1.6-1: Acronyms

Acronyms	Meaning
CCW	Component Cooling Water
CE	Combustion Engineering
CETNA	Core Exit Thermocouple Nozzle Assembly
CF	Chemistry Factor
Cfm	Cubic-Feet per Minute
CFR	Code Of Federal Regulations
CFS	Chemical Feed
CGS	Argon Gas Supply System
CGCS	Combustible Gas Control Systems
CIS	Containment Isolation System
CISI	Containment Inservice Inspection
CLB	Current Licensing Basis
CLS	Chlorination System
CMAA	Crane Manufacturers Association of America
CMTR	Certified Material Test Report
COLR	Core Operating Limits Report
CP PowerCo	Comanche Peak Power Company LLC
CPNPP CPSES	Comanche Peak Nuclear Power Plant (Aka) Comanche Peak Steam Electric Station
CPS	Condensate Polishing System
CR	Condition Report
CRD	Control Rod Drive
CRE	Control Room Envelope

Table 1.6-1: Acronyms

Acronyms	Meaning
CRDM	Control Rod Drive Mechanism
CRGT	Control Rod Guide Tube
CSB	Core Support Barrel
CSS	Containment Spray System
CST	Condensate Storage Tank
CUF	Cumulative Usage Factor
CUF_{adj}	Adjusted Cumulative Usage Factor
CUF_{EN}	Environmentally Adjusted Cumulative Usage Factor
CUI	Corrosion Under Insulation
CVCS	Chemical And Volume Control System
CVS	Condenser Vacuum And Waterbox Priming System
CW	Circulating Water
CWS	Circulating Water System
DA	Degradation Assessment
DBA	Design Basis Accident or Design Basis Assurance
DBD	Design Basis Document
DBE	Design Basis Event
DC	Direct Current
DG	Diesel Generator
DGA	Diesel Generator Area
DGAIES	Diesel Generator Combustion Air Intake and Exhaust System
DGB	Diesel Generator Building

Table 1.6-1: Acronyms

Acronyms	Meaning
DGFOSTS	Diesel Generator Fuel-Oil Storage and Transfer System
DGJWS	Diesel Generator Cooling Water System
DGLOS	Diesel Generator Lube Oil System
DGRVS	Diesel Generator Room Ventilation Sub-System
DGSAS	Diesel Generator Starting System
DMW	Dissimilar Metal Weld
DNBR	Departure from Nucleate Boiling Ratio
DRMWS	Demineralized and Reactor Makeup Water System
EAF	Environmentally Assisted Fatigue
ECB	Electrical and Control Building
ECCS	Emergency Core Cooling System
EDG	Emergency Diesel Generator
EEQ	Environmental Equipment Qualification
EEQSP	Environmental Equipment Qualification Summary Package
EFPY	Effective Full Power Year
EIC	Electrical and I&C
EOC	Extent of Condition
EOLE	End-of-License Extension
EPR	Ethylene Propylene Rubber
EPRI	Electric Power Research Institute
EQ	Environmental Qualification
EQMM	Environmental Qualification Maintenance Manual

Table 1.6-1: Acronyms

Acronyms	Meaning
ESF	Engineered Safety Feature
ESFAS (SIAS)	Engineered Safety Features Actuation System (Safety Injection Actuation System)
EVT	Enhanced Visual Examination
F (°F, degF)	Degrees Fahrenheit
FAC	Flow-Accelerated Corrosion
F_{adj}	Adjusted Environmentally Assisted Fatigue Correction Factor
FB	Fuel Building
FD	Flow Diagram
FDS	Filter/Demineralizer System
FE	Further Evaluation
F_{en}	Environmentally Assisted Fatigue Correction Factor
FHA	Fire Hazards Analysis
FIBV	Feedwater Isolation Bypass Valve
FIV	Flow-Induced Vibration
FLR	Full Life Rate
FME	Foreign Material Exclusion
FOL	Facility Operating License
FOSAR	Foreign Object Search and Retrieval
FOST	Fuel Oil Storage Tank
FP	Fire Protection

2.0. SCOPING AND SCREENING METHODOLOGY FOR IDENTIFYING STRUCTURES AND COMPONENTS SUBJECT TO AMR, AND IMPLEMENTATION RESULTS

This section describes the process for identifying and determining the CPNPP SSCs that are included in the scope of LR. Passive, long-lived SSCs in the scope of LR are subject to AMR in the CPNPP IPA. For those SSCs within the scope of LR, 10 CFR 54.21(a)(1) requires the LR applicant to identify and list the structures and components subject to AMR. Furthermore, 10 CFR 54.21(a)(2) requires that the methods used to identify these structures and components be described and justified. The information in this section satisfies these requirements.

Scoping is the process of identifying the plant systems and structures that are determined to be in the scope of LR in accordance with 10 CFR 54.4. The intended functions that are the bases for including the systems and structures within the scope of LR are also identified during the scoping portion of the LRA process. Screening is the process of determining which components associated with the in-scope systems and structures are subject to AMR in accordance with 10 CFR 54.21(a)(1) requirements.

A description of the CPNPP scoping and screening process is provided in Section 2.1. The plant level scoping results which identify the systems and structures within the scope of LR are provided in Section 2.2. The screening results which identify components subject to AMR for mechanical systems, structures, and Electrical and I&C (EIC) systems in the scope of LR are provided in Sections 2.3, 2.4, and 2.5, respectively.

2.1. SCOPING AND SCREENING METHODOLOGY

2.1.1. Introduction

The LR rule (10 CFR Part 54) defines the scope of LR using three criteria. 10 CFR 54.4(a) requires SSCs to be within the scope of LR if they are —

(1) Safety related systems, structures, and components, which are those relied upon to remain functional during and following design-basis events (as defined in 10 CFR 50.49 (b)(1)) (Reference 1.7.16) to ensure the following functions --

(i) The integrity of the reactor coolant pressure boundary;

(ii) The capability to shut down the reactor and maintain it in a safe shutdown condition; or

(iii) The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposures comparable to those referred to in §50.34(a)(1), §50.67(b)(2), or §100.11 of this chapter, as applicable.

(2) All non-safety related systems, structures, and components whose failure could prevent satisfactory accomplishment of any of the functions identified in paragraphs (1)(i), (ii), or (iii) of this section.

(3) All systems, structures, and components relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for fire protection (10 CFR 50.48), environmental qualification (10 CFR 50.49), pressurized thermal shock (10 CFR 50.61), anticipated transients without scram (10 CFR 50.62), and station blackout (10 CFR 50.63).

NEI 95-10, Industry Guidelines for Implementing the Requirements of 10 CFR Part 54 – The License Renewal Rule, Revision 6, provides industry guidance for determining what SSCs are in the scope of LR. The process, used to determine the systems and structures in the scope of LR for the CPNPP units, follows the recommendations of NEI 95-10.

The initial step in the scoping process was to define the entire plant in terms of systems and structures. Each of these systems and structures were evaluated against the scoping criteria in 10 CFR 54.4(a)(1), (a)(2), and (a)(3) to determine if the system or structure should be considered in the scope of LR. The intended function(s) that are the basis for including each system and structure within the scope of LR were also identified.

A mechanical system or structure is included within the scope of LR if any portion of the system or structure meets one or more of the scoping criteria of 10 CFR 54.4. Structural commodities associated with mechanical systems, such as pipe hangers and supports, are evaluated with the structural bulk commodities along with insulation on mechanical system piping and components. All EIC systems are included within the scope of LR under an in-scope bounding approach (ISBA) except for the Meteorological Instrumentation and Security Systems which were specifically scoped out. Mechanical systems which contain EIC components are included in the evaluation of EIC components, regardless of whether the mechanical system is included within scope. The bases for EIC systems to be included within scope of LR are not identified since the bounding approach makes it unnecessary to determine if an EIC system meets any of the criteria of 10 CFR 54.4. The mechanical, structural and EIC systems and components within scope of LR were then further evaluated to determine the system components that support the identified system intended function(s).

Figure 2.1-1 provides a flowchart of general scoping and screening processes used for mechanical systems, structures, and EIC systems.

Figure 2.1-2 provides a further flowchart of the various aspects of the process for evaluating the non-safety affecting safety scoping criterion, 10 CFR 54.4(a)(2).

Figure 2.1-1 CPNPP Scoping and Screening Flow Chart

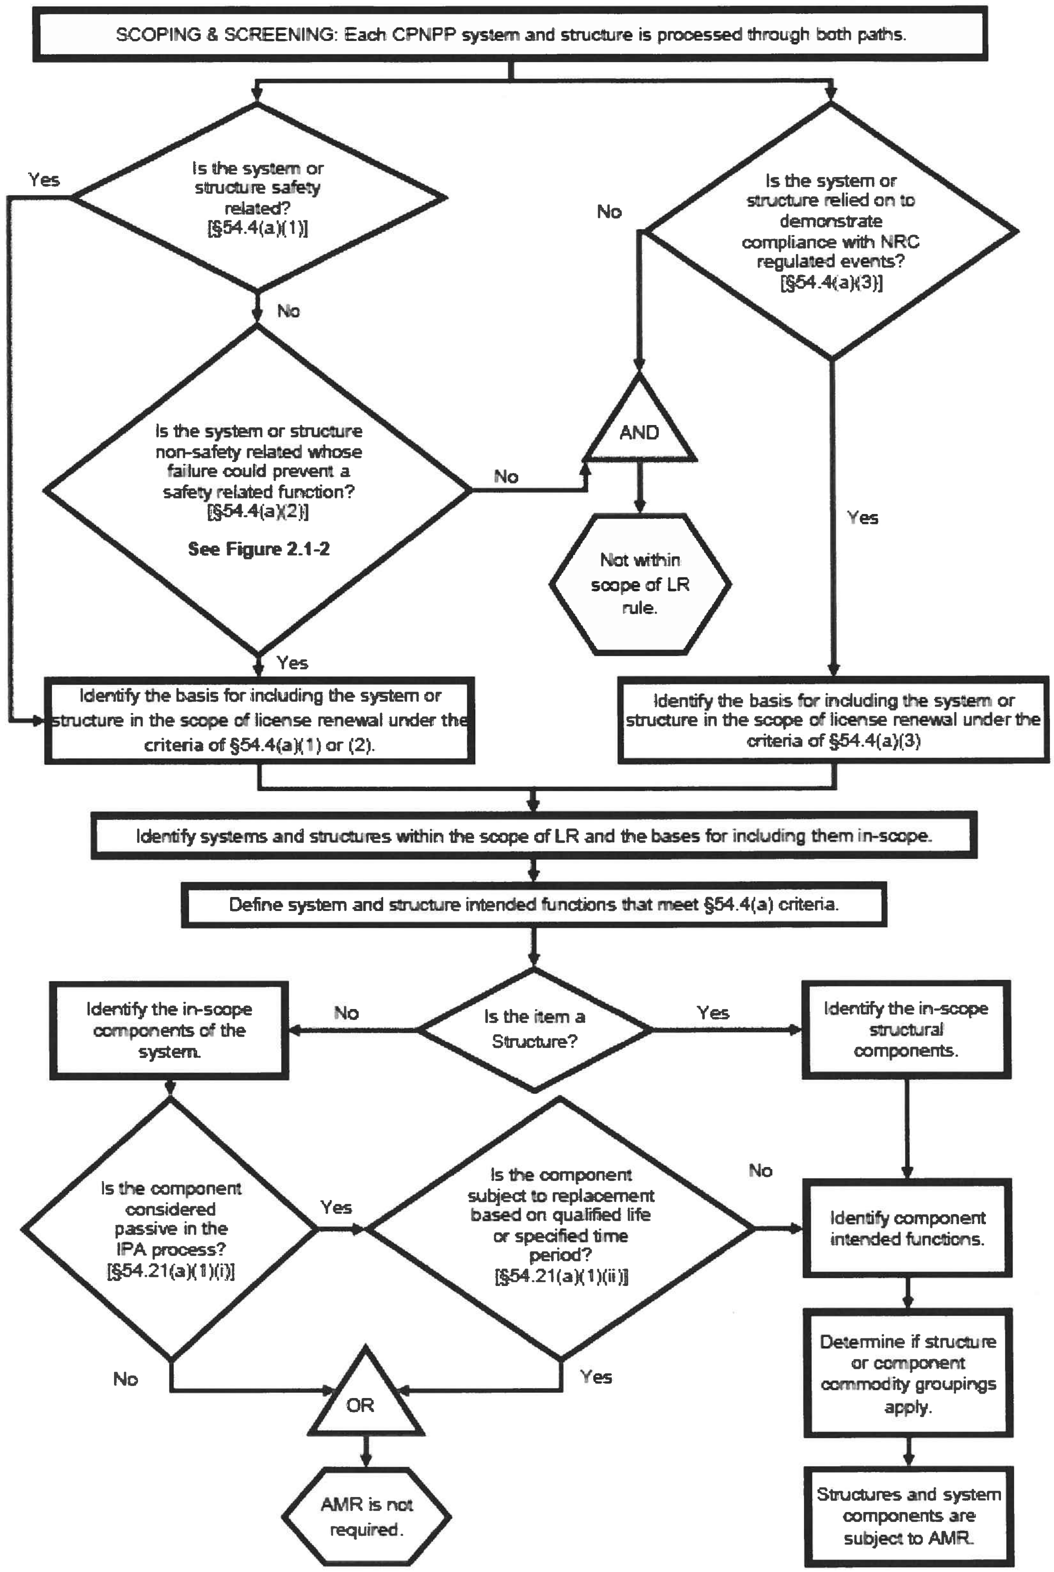

Figure 2.1-2 CPNPP 10 CFR 54.4(a)(2) Evaluation Methodology

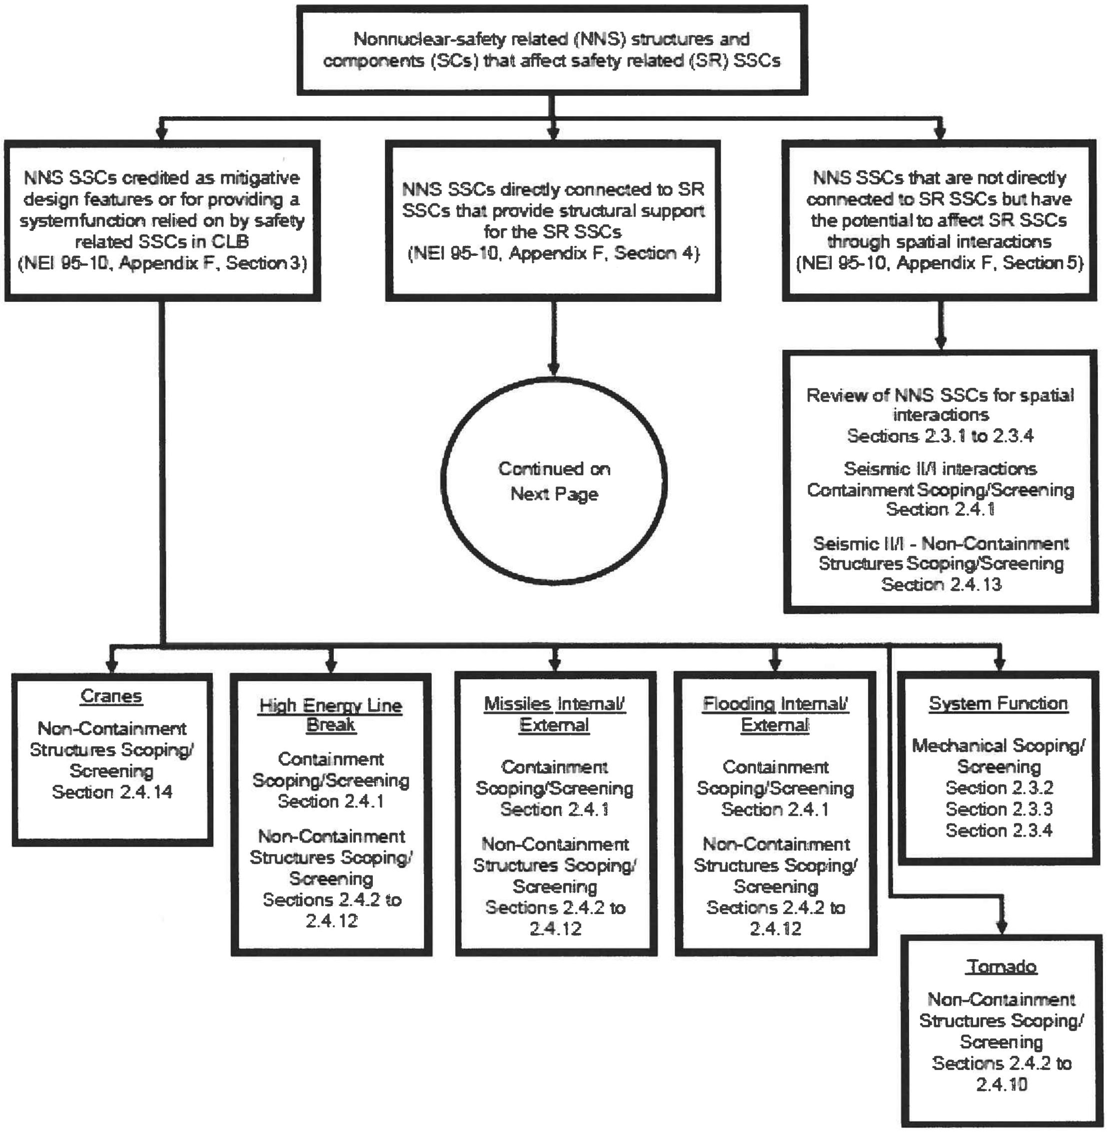

Figure 2.1-2 CPNPP 10 CFR 54.4(A)(2) (Continued)

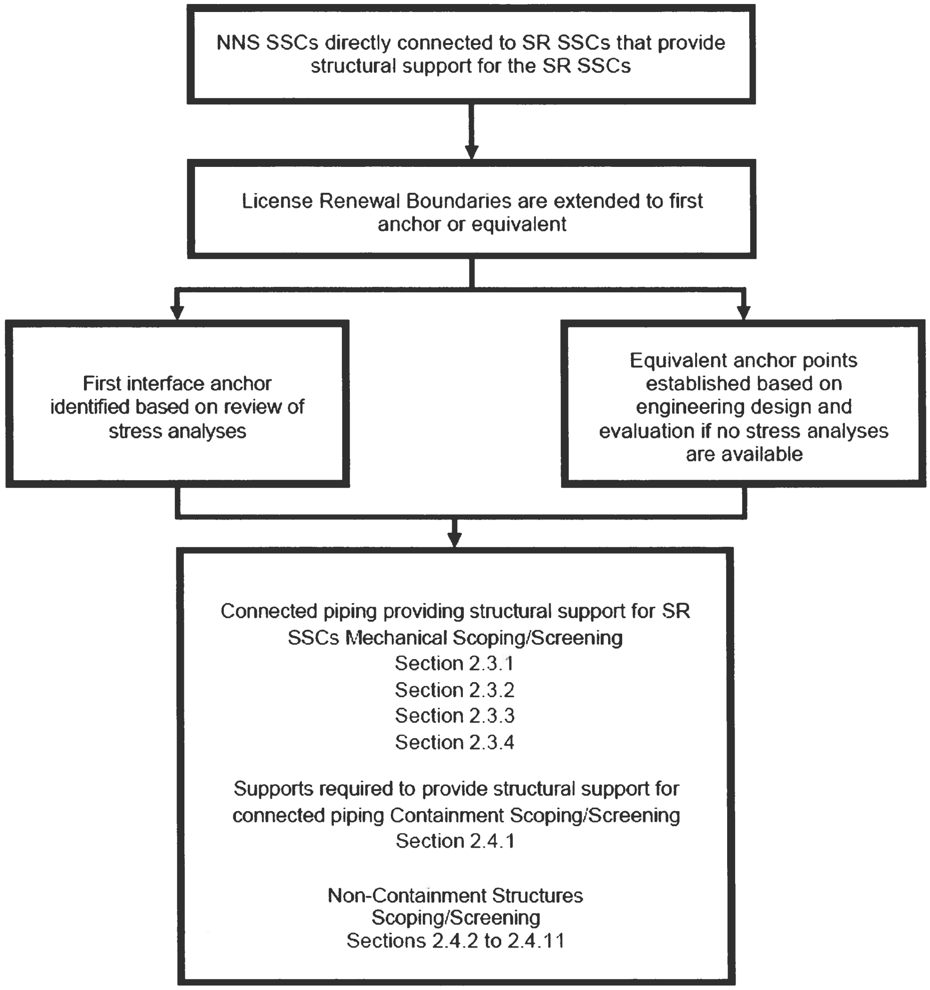

2.1.2. Information Sources Used for Scoping and Screening

Various current licensing bases (CLB) and design basis information sources for CPNPP were utilized in the scoping process and screening process. These sources were used to determine if there was a basis for including each CPNPP system and structure in the scope of LR. The CLB for CPNPP is consistent with the definition provided in 10 CFR 54.3.

These source documents are available in hard copy or electronic format. Document records such as licensing correspondence and NRC Safety Evaluation Reports (SERs) are available in a searchable database, such that applicable documents can be identified and located by searching the appropriate topic.

2.1.2.1. Final Safety Analysis Report

The Final Safety Analysis Report (FSAR) used for the scoping process describes the design, construction, and operation of a two-unit nuclear power plant designated as the CPNPP, Operating Licenses NPF-87 and NPF-89 for Units 1 and 2, respectively. This report follows the format recommended by RG 1.70, Revision 2, Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants (Reference 1.7.17). The FSAR provided significant input for the system and structure scoping process.

2.1.2.2. Fire Protection Report

The Fire Protection Report (FPR) documents the comprehensive study of the fire protection (FP) features and fire safe shutdown capabilities for CPNPP Units 1 and 2. The overall approach for FP considers preventing, detecting, and suppressing fires along with maintaining plant ability to perform fire safe shutdown functions. The FPR includes the Fire Hazards Analysis Report and the Fire Safe Shutdown Analysis Report.

2.1.2.3. Master Equipment List

The CPNPP Master Equipment List (MEL) is a comprehensive list of the components contained within each system. The MEL, combined with information in the CPNPP FSAR, was used to develop the total list of systems and structures included within the scope of LR.

2.1.2.4. Maintenance Rule Database

The Maintenance Rule Database documents the results of Maintenance Rule scoping for CPNPP systems and structures. The Maintenance Rule Database provided an additional source of information to identify bases for including systems and structures within the scope of LR.

2.1.2.5. Engineering Drawings

Engineering drawings at CPNPP provide SSC configuration details and safety classification information. These drawings were used to determine SSC functional requirements to determine if there was a basis for including the SSCs in the scope of LR.

2.1.2.6. Design Basis Documents

Design basis documents (DBDs) provide the design intent of a given system or structure where they exist. These DBDs were utilized to determine intended functions of a system and structure and provided significant input to the scoping process.

2.1.2.7. Other CLB References

NRC SERs and Supplements include NRC staff review of CPNPP licensing submittals. Some of these documents may contain licensee commitments.

Licensing correspondence includes relief requests, Licensee Event Reports (LERs), and responses to NRC communications such as NRC Inspection and Enforcement Bulletins (IEBs), generic letters (GLs), or enforcement actions. Some of these documents may contain licensee commitments.

2.1.3. Technical Reports

Technical reports were prepared in support of the CPNPP LRA. Engineers experienced in nuclear plant systems, programs, and operations prepared the reports. Reports contain technical evaluations and bases for decisions or positions associated with LR requirements. Reports are prepared, reviewed, and approved in accordance with controlled project procedures, and are based on the CPNPP CLB source documents described in Section 2.1.2.

2.1.3.1. License Renewal Systems and Structures List

One of the first steps necessary to begin the LR scoping process was to identify a comprehensive list of systems and structures to be evaluated for a LR scoping determination. Review of a variety of document sources that identify systems and structures at CPNPP was conducted and a comprehensive list of LR systems and structures was prepared using the CPNPP FSAR, CPNPP system and structure DBDs, and the CPNPP MEL. The list in the MEL was evaluated against the CPNPP FSAR, plant design drawings, the Maintenance Rule database, CPNPP systems and structure DBDs, and other plant CLB documents. Plant systems and structures were arranged into groupings for scoping reviews. Components evaluated as commodity groups were also identified. This list is the first step in the CPNPP LRA scoping process and assures all plant structures and components included in the scoping review are associated with a system, structure, or commodity group.

2.1.3.2. License Renewal Scoping

The scoping process and evaluations associated with the CPNPP LRA are documented in a CPNPP technical report. The CPNPP systems and structures list discussed in Section 2.1.3.1 were evaluated to determine if there was a basis for including each system or structure in the scope of LR, per the criteria described in 10 CFR 54.4(a)(1), (a)(2), or (a)(3) as depicted in Figures 2.1-1 and 2.1-2. During this process, the CPNPP systems and structures were grouped into the following categories:

- Reactor Vessel, Internals, and Reactor Coolant System
- Engineered Safety Features
- Auxiliary Systems
- Steam and Power Conversion Systems
- Containments, Structures, and Component Supports
- Electrical and Instrumentation and Control Systems

The grouping of systems and structures into these categories is based on the intended functions of the system and structure as described in the CPNPP FSAR and CPNPP system DBDs, and consistent with guidance of NUREG-1801.

Each mechanical system and structure was evaluated to determine if the individual system and structure was in the scope of LR (and the basis). If the individual system or structure did not meet any of the criteria of 10 CFR 54.4(a)(1), (a)(2), or (a)(3) then a justification for the exclusion of the system or structure from the scope of LR was provided.

All EIC Systems (except Meteorological Instrumentation and Security Systems) are automatically considered in scope. Additionally, all EIC components that are contained within mechanical systems are automatically in scope, regardless of whether the mechanical system is determined to be in scope. Since this bounding approach is utilized, no bases are provided for including EIC systems and components in the scope of LR.

Certain structures and equipment were excluded at the outset because they are not considered to be SSCs that are part of the CLB and/or do not have design or functional requirements related to the 10 CFR 54.4(a)(1), (a)(2), or (a)(3) scoping criteria. These SSCs include driveways and parking lots, temporary equipment, health physics equipment, portable measuring and testing equipment, tools, and motor vehicles.

2.1.3.3. License Renewal Operating Experience

Site and industry OE associated with CPNPP LR are documented in CPNPP technical reports. Site and industry OE is used primarily to confirm the applicability of typical material and environment based aging effects to CPNPP and ensure any aging effects specific to CPNPP are evaluated. Also, the lessons-learned from recent applicants for LR or subsequent LR (SLR) may provide OE germane to CPNPP LR and are considered. Any such lessons-learned pertinent to system and structure scoping or SSC screening are addressed in the technical reports described in Section 2.1.3.2 above, and Section 2.1.3.4 below, respectively.

2.1.3.4. License Renewal Screening and Aging Management Review

For the systems and structures in the scope of CPNPP LR, the determination of passive, long-lived components and commodities, their function(s), and the associated AMRs are documented in CPNPP technical reports for individual or a collection of systems, structures, or bulk (EIC) and structural commodities. The methodology for screening, determining passive and long-lived components and their intended functions, is described in Section 2.1.6 below. AMR considerations generically applicable to CPNPP SSCs are addressed in Section 3.0 below.

2.1.3.5. License Renewal Aging Management Programs

The effectiveness of existing or new site programs identified in Section 3, Aging Management Review Results, as AMPs for LR, in managing the identified effects of aging are documented in individual technical reports that serve as AMP basis documents. These AMP basis documents also consider site and industry OE as part of the effectiveness demonstration. The demonstration of effectiveness for each credited AMP is summarized in Appendix B, "Aging Management Programs".

2.1.4. INTERIM STAFF GUIDANCE DISCUSSION

NRC staff LR guidance documents pertinent to CPNPP LR include:

- NUREG-1800, Revision 2, Standard Review Plan for Review of License Renewal Applications for Nuclear Power Plants; and
- NUREG-1801, Revision 2, Generic Aging Lessons Learned (GALL) Report.

In addition, Interim Staff Guidance (ISG) documents issued by the NRC after the above guidance documents constitute an update or clarification of the guidance contained in those documents. The following is a listing of issued ISG updates/clarifications of NUREG-1800 and/or NUREG-1801:

LR-ISG-2011-01 Aging Management of Stainless Steel Structures and Components in Treated Borated Water, Revision 1 (Reference 1.7.18)

LR-ISG-2011-02 Aging Management Program for Steam Generators (Reference 1.7.19)

LR-ISG-2011-05 Ongoing Review of Operating Experience (Reference 1.7.20)

LR-ISG-2012-01 Wall Thinning Due to Erosion Mechanisms (Reference 1.7.21)

LR-ISG-2012-02 Aging Management of Internal Surfaces, Fire Water Systems, Atmospheric Storage Tanks, and Corrosion Under Insulation (Reference 1.7.22)

LR-ISG-2013-01 Aging Management of Loss of Coating or Lining Integrity for Internal Coatings/Linings on In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (Reference 1.7.23)

LR-ISG-2015-01 Changes to Buried and Underground Piping and Tank Recommendations (Reference 1.7.24) (replaces LR-ISG-2011-03)

LR-ISG-2016-01 Changes to Aging Management Guidance for Various Steam Generator Component (Reference 1.7.25)

SLR-ISG-2021-01-PWRVI Updated Aging Management Criteria for Reactor Vessel Internals Components for Pressurized Water Reactors (supersedes in total the previous guidance in LR-ISG-2011-04) (Reference 1.7.26)

Other NRC guidance documents for SLR (60 to 80 years of operation) are not directly applicable to CPNPP LR (40 to 60 years of operation). However, these guidance documents, including approved SLR-ISGs, contain OE that may be applicable to CPNPP LR and are, therefore, considered in Section 2.1.4.10.

The following sections summarize how each of the LR-ISGs are addressed in the CPNPP LRA.

2.1.4.1. LR-ISG-2011-01, Aging Management of Stainless Steel Structures and Components in Treated Borated Water, Revision 1

This LR-ISG provides one acceptable approach to managing the aging effects of stainless steel structures and components exposed to treated borated water, that includes physical verification of the effectiveness of preventive programs. The updated guidance has been considered in the CPPNP IPA as reflected in Section 3, “Aging Management Review Results”, and in Appendix B, “Aging Management Programs”. The One-Time Inspection (B.2.3.19) AMP, when appropriate, is credited to verify the effectiveness of the Water Chemistry (B.2.3.2) AMP for managing aging effects of stainless steel structures and components within the scope of LR that are exposed to treated borated water. The One-Time Inspection AMP is addressed in Section B.2.3.19 and the Water Chemistry (B.2.3.2) AMP is addressed in Section B.2.3.2.

2.1.4.2. LR-ISG-2011-02, Aging Management Program for Steam Generators

This LR-ISG recommends the adoption of Revision 3 of NEI 97-06, “Steam Generator Program Guidelines” (Reference 1.7.27). CPNPP has considered the updated guidance in the IPA as reflected in Section 3.1, “Aging Management of Reactor Vessel, Internals, and Reactor Coolant System,” and in Appendix B, “Aging Management Programs”. The Steam Generators AMP is addressed in Section B.2.3.10.

2.1.4.3. LR-ISG-2011-05, Ongoing Review of Operating Experience

This LR-ISG revises the NUREG-1800 acceptance criteria and review procedure to better address the ongoing review of OE with respect to LR AMP effectiveness. CPNPP incorporates the guidance presented in this LR-ISG. Ongoing review of OE is addressed in Appendix A, Final Safety Analysis Report Supplement, Section A.1.4 and Appendix B, Aging Management Programs, Section B.1.4, “Operating Experience”.

2.1.4.4. LR-ISG-2012-01, Wall Thinning Due to Erosion Mechanisms

This LR-ISG provides an acceptable approach to manage the effects of wall-thinning due to mechanisms other than Flow-Accelerated Corrosion (B.2.3.8) (FAC), i.e., various forms of erosion that have caused problems in the past and continue to be encountered in some operating reactor systems. The updated guidance has been considered in the CPNPP IPA as reflected in the aging management results presented in Section 3 and the AMP descriptions presented in Appendix B, Section B.2.3.8. CPNPP Flow-Accelerated Corrosion (B.2.3.8) AMP addresses similar wall-thinning mechanisms and will adopt the guidance of this LR-ISG relative to erosion mechanisms.

2.1.4.5. LR-ISG-2012-02, Aging Management of Internal Surfaces, Fire Water Systems, Atmospheric Storage Tanks, and Corrosion Under Insulation

This LR-ISG provides an acceptable approach for managing the aging of components that are a) internal surfaces not managed by another program, b) elastomers, c) above ground metallic tanks, d) susceptible to blockage in fire water systems, e) insulated surfaces, or f) susceptible to recurring internal corrosion. The updated guidance has been considered in the CPNPP IPA as reflected in the AMR results presented in Section 3, and in the corresponding AMP descriptions in Appendix B, Section B.2.3.12, "Closed Treated Water Systems", Section B.2.3.16, "Fire Water System", Section B.2.3.22," External Surfaces Monitoring of Mechanical Components", and Section B.2.3.24, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components".

2.1.4.6. LR-ISG-2013-01, Aging Management of Loss of Coating or Lining Integrity for Internal Coatings/Linings on In-Scope Piping, Piping Components, Heat Exchangers, and Tanks

This LR-ISG provides guidance on an acceptable approach to the management of coatings/linings internal to mechanical components in the scope of LR. The updated guidance has been considered in the CPNPP IPA as reflected in the AMR results in Section 3 and the AMP description in Appendix B, Section B.2.3.28, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers and Tanks".

2.1.4.7. LR-ISG-2015-01, Changes to Buried and Underground Piping and Tank Recommendations (LR-ISG-2011-03 has been replaced by LR-ISG-2015-01)

This LR-ISG provides guidance on an acceptable approach to managing the aging on external surfaces of buried components and for managing the aging of components that are "underground." Below-grade tunnels, pits, manholes, valve boxes, and vaults comprise "underground." The updated guidance has been considered in the CPNPP IPA as reflected in the AMR results in Section 3, and the AMP description in Appendix B. The Buried and Underground Piping and Tanks Inspection program is described in Section B.2.3.27.

2.1.4.8. LR-ISG-2016-01, Changes to Aging Management Guidance for Various Steam Generator Components

This LR-ISG provides changes relative to managing of cracking due to primary water stress corrosion cracking (PWSCC) of nickel alloy sub-components on the primary side of the steam generators (SGs), such as the divider plate. This updated guidance has been considered in the CPNPP IPA as reflected in the AMR results in Section 3.1, "Aging Management of Reactor Vessel, Internals, and Reactor Coolant

System", and in Appendix B, "Aging Management Programs". The Steam Generators AMP is addressed in Section B.2.3.10.

2.1.4.9. SLR-ISG-2021-01-PWRVI Updated Aging Management Criteria for Reactor Vessel Internals Components for Pressurized Water Reactors

This SLR-ISG provides a framework to ensure that age-related degradation and aging of pressurized water reactor (PWR) reactor vessel internal (RVI) components are adequately addressed and recommends the adoption of EPRI Materials Reliability Program (MRP) document MRP-227, Revision 1-A, Pressurized Water Reactor Internals Inspection and Evaluation Guidelines (Reference 1.7.28) for management of PWR RVI components. This framework supersedes in total the previous guidance in LR-ISG-2011-04, which is related to NUREG-1800 Revision 2 and NUREG-1801 Revision 2. The updated guidance has been considered in the CPNPP IPA as reflected in Section 3.1, "Aging Management of Reactor Vessel, Internals, and Reactor Coolant System", and in the PWR Vessel Internals AMP in Section B.2.3.7.

2.1.4.10. Operating Experience in Subsequent License Renewal Guidance

Other SLR (60 to 80 years of operation) guidance documents are not applicable to CPNPP LR. However, these documents are treated as OE that may be relevant to CPNPP LR. This OE has been considered in the CPNPP IPA and utilized as appropriate, on a limited basis. The AMR results in Section 3 include a plant-specific note for line items that include clarification from SLR OE. Similarly, AMP descriptions in Appendix B indicate when an element(s) of the program is clarified by SLR OE.

The SLR guidance documents that contain potential OE applicable to CPNPP include:

- NUREG-2191, Generic Aging Lessons Learned for Subsequent License Renewal (GALL-SLR) (References 1.7.29);
- NUREG-2192, Standard Review Plan for Review of Subsequent License Renewal Applications for Nuclear Power Plants (References 1.7.30);
- SLR-ISG-2021-02-MECHANICAL, *Updated Aging Management Criteria for Mechanical Portions of Subsequent License Renewal Guidance* (Reference 1.7.31);
- SLR-ISG-2021-03-STRUCTURES, *Updated Aging Management Criteria for Structures Portions of Subsequent License Renewal Guidance* (Reference 1.7.32); and
- SLR-ISG-2021-04-ELECTRICAL, *Updated Aging Management Criteria for Electrical Portions of Subsequent License Renewal Guidance* (Reference 1.7.33).

2.1.5. SCOPING PROCEDURE

The scoping process is the systematic process used to identify the CPNPP systems and structures within the scope of the LR rule. The scoping process was performed at the system and structure level, in accordance with the scoping criteria identified in 10 CFR 54.4(a). Bases for determining if a system or structure is in the scope of LR, the intended functions, were identified from a review of the pertinent CLB and design documents. System and structure scoping evaluations are documented and have been retained in the CPNPP LR technical reports. The system and structure scoping results are provided in Section 2.2.

The CPNPP scoping process began with the development of a comprehensive list of plant systems and structures as described in LR technical reports. These systems and structures were grouped into the following categories to support further evaluation (FE) and the screening process:

- Reactor Vessel, Internals, and Reactor Coolant System
- Engineered Safety Features
- Auxiliary Systems
- Steam and Power Conversion Systems
- Containments, Structures, and Component Supports
- Electrical, Instrumentation and Control Systems

Each CPNPP system and structure was then evaluated to determine if it fell within the scope of LR, using the criteria of 10 CFR 54.4(a). These criteria are briefly identified as follows:

- 10 CFR 54.4(a)(1) – Nuclear Safety Related or Safety Related
- 10 CFR 54.4(a)(2) – Non-Nuclear Safety Related (NNS) affecting Nuclear Safety Related
- 10 CFR 54.4(a)(3) – Regulated Events
    - Fire Protection (FP) (10 CFR 54.48)
    - Environmental Qualification (EQ) (10 CFR 54.49)
    - Pressurized Thermal Shock (PTS) (10 CFR 50.61)
    - Anticipated Transient Without Scram (ATWS) (10 CFR 50.62)
    - Station Blackout (SBO) (10 CFR 50.63)

2.1.5.1. Nuclear Safety Related – 10 CFR 54.4(a)(1)

In accordance with 10 CFR 54.4(a)(1), the SSCs within the scope of LR include:

> *Safety related systems, structures, and components, which are those relied upon to remain functional during and following design-basis events (as defined in 10 CFR 50.49 (b)(1)) to ensure the following functions—*
>
> *(i) The integrity of the reactor coolant pressure boundary;*
>
> *(ii) The capability to shut down the reactor and maintain it in a safe shutdown condition; or*

(iii) The capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposures comparable to those referred to in §50.34(a)(1), § 50.67(b)(2), or § 100.11 of this chapter, as applicable.

The CPNPP definitions of nuclear safety related and safety related (which are synonymous at CPNPP) SSCs do not address the exposure guidelines referred to in 10 CFR 50.67(b)(2).

Section 50.67(b) reads,

(1) A licensee who seeks to revise its current accident source term in design basis radiological consequence analyses shall apply for a license amendment under §50.90. The application shall contain an evaluation of the consequences of applicable design basis accidents previously analyzed in the safety analysis report.…

CPNPP has retained its original accident source term in radiological consequence analyses and the offsite dose limits discussed in Subpart A of 10 CFR 100 are applicable to CPNPP, whereas a revised accident source term is not. Furthermore, 10 CFR 50.34(a)(1)(i) is applicable to CPNPP as the construction permit was issued before January 10, 1997. 10 CFR 50.34(a)(1)(i) indicates "special attention should be directed to the site evaluation factors in part 100 of this chapter" (10 CFR Part 50). Therefore, the extent to which these limits affect the CPNPP definitions of nuclear safety related and safety related SSCs are consistent with the definition of a SR SSC in 10 CFR 54.4(a)(1) and with the definition of design basis events (DBEs) in 10 CFR 50.49(b)(1).

As described in FSAR Section 3.2.2, "Fluid system components important to safety are classified in accordance with the American National Standards Institute (ANSI) N18.2-1973, Nuclear Safety Criteria for the Design of Stationary PWR Plants classification except as described below. This classification system is compatible with requirements of NRC RG 1.26 and is submitted as an alternate acceptable method of meeting the intent of NRC RG 1.26."

As described in FSAR Section 3.2.1.1, "The plant structures, Reactor Coolant System, engineered safety features, and safety related systems and components are identified and classified in accordance with the seismic requirements of General Design Criterion 2 of Appendix A to 10 CFR Part 50, General Design Criteria for Nuclear Power Plants. NRC RG 1.29 designates those structures, systems, and components which must remain functional during the safe shutdown earthquake (SSE) as Seismic Category I items."

FSAR Table 17A-1, along with the MEL, identifies safety related SSCs. Safety related CPNPP systems and components, consistent with their function, are designated as Safety Class 1, 2, 3 with components or their portions designed to the ASME B&PV Code, Section III, and subject to QA programs. Some demineralizers, heat exchangers and other components that are Safety Class 3 do not expressly meet the 10 CFR 54.4(a)(1) criteria yet are included in the scope of license renewal (LR). These components are described in FSAR Table 17A-1 and include:

- Mixed Bed Demineralizer;
- Cation Bed Demineralizer;
- Moderating Heat Exchanger;
- Letdown Chiller Heat Exchanger (Tube side);
- Letdown Reheat Heat Exchanger (Shell side);
- Thermal regeneration demineralizers;
- Associated piping, valves, etc.; as well as
- Burnable poison rod assemblies and Primary source rods.

Mechanical systems with components that perform a safety function are classified as nuclear safety related, meet 10 CFR 54.4(a)(1), and are included in the scope of LR. Likewise, Seismic Category I structures meet the 10 CFR 54.4(a)(1) criteria and are in the scope of LR. EIC systems, and EIC portions of other systems, are included within the scope of LR under an ISBA as described in Section 2.1.1.

Safety functions that are the basis for including an SSC in scope are identified by reviewing the FSAR, DBDs, engineering drawings, the MR basis document, and other CLB and design documents.

2.1.5.2. Non-Nuclear Safety Related Affecting Nuclear Safety Related – 10 CFR 54.4(a)(2)

In accordance with 10 CFR 54.4(a)(2), the SSCs within the scope of LR include:

- *All nonsafety-related systems, structures, and components whose failure could prevent satisfactory accomplishment of any of the functions identified in paragraphs (a)(1)(i), (ii), or (iii) of this section.*

This scoping criterion required an assessment of non-nuclear safety related (NNS) SSCs with respect to the following categories:

- Functional support for nuclear safety related SSC 10 CFR 54.4(a)(1) functions
- Connected to and provide structural support for nuclear safety related SSCs
- Potential for spatial interactions with nuclear safety related SSCs

Each of these categories is discussed below:

Functional Support for Nuclear Safety Related SSC 10 CFR 54.4(a)(1) Functions

At CPNPP, non-structural SSCs that perform a function that supports a safety function are classified as nuclear safety related, with few exceptions. Safety Class 3 fluid system pressure boundary components include those that are necessary to provide or support a safety system function. Multiple systems supporting safety functions are identified as nuclear safety related in FSAR Table 17A-1.

SSCs that are NNS and in scope per 10 CFR 54.4(a)(2) with a function credited in the CLB include the protective (mitigative) features installed in Seismic Category I structures to protect nuclear safety related SSCs from (external or internal) flooding, tornadoes, or pipe ruptures or excess temperatures that might occur, or in non-seismic structures to prevent/mitigate flooding of adjacent Seismic Category I structures. These mitigative features are NNS commodities and have a credited function described in the FSAR, such as:

- tornado protection design features including tornado vents (FSAR Sections 2.3.1.2, 2.3.2.3, 3.3.2, & 3.5.1.4),
- watertight doors, water stops, curbs, stop gates and sumps for flood protection (discussed in FSAR Section 3.4.1),
- missile barriers inside and outside Containment (RCB) (FSAR Sections 3.5.1.2.3, 3.5.1.1.2, respectively),
- high energy line break (HELB), moderate energy line break/crack (MELB/MELC) barriers and shields and pipe whip restraints (FSAR Section 3.6B); as well as
- insulation on components in nuclear safety related and engineered safety feature pump rooms credited for the heat removal capability of area room coolers during pump operation (FSAR 9.4.5.1), and
- insulation on Reactor Coolant System piping and in high temperature penetration assemblies that are implicitly credited with maintaining Containment and biological shield wall local concrete temperatures at acceptable levels (FSAR 3.8.3.4.8).

The CPNPP FSAR and other CLB documents were reviewed to identify NNS SSCs that are credited with supporting satisfactory accomplishment of a nuclear safety related function. NNS SSCs credited in CLB documents to support a nuclear safety related function are included within the scope of LR, and the function is listed as an intended function for 10 CFR 54.4(a)(2) for the system.

The following were identified as a system function performed by NNS components whose failure could prevent satisfactory accomplishment of a safety function:

- NNS backwater valves within the floor drain system prevent water from backing up through drain lines and possibly impairing the function of nuclear safety related equipment (FSAR Section 9.3.3.2),
- NNS ball float devices within the floor drain system prevent steam propagation or unfiltered air inleakage to other interconnecting areas and are provided as necessary for the protection of essential systems and components (FSAR Section 9.3.3.2),
- Circulating Water System (CWS) pumps trip prior to overflowing the TB pit, in order to prevent flooding of nuclear safety related equipment in the adjacent ECB (FSAR Section 10.4.5.3),
- The Reactor Coolant Pipe Penetration Cooling in Primary Shield Wall system (a Containment Ventilation subsystem) is designed to dissipate heat conducted to the supports by the reactor coolant lines utilizing forced convection to prevent dehydration of concrete (FSAR 9.4A.1.7),
- Additionally, Fire Protection System (FPS) hose stations and components in the spent fuel area can also supply makeup water in excess of the boil-off rate to the spent fuel pools (SFPs) if normal sources are unavailable (FSAR 9.5.1.4.2.d). These components are in the scope of LR per 10 CFR 54.4(a)(3).

Connected to and Provide Structural Support for Nuclear Safety Related SSCs

Based on the guidance in NEI 95-10, systems containing NNS SSCs that are directly connected to nuclear safety related SSCs (typically piping), and the associated structural supports (anchors) satisfy the criterion of 10 CFR 54.4(a)(2) and are within the scope of LR.

NNS piping and process tubing directly connected to (and providing structural support for) nuclear safety related piping and components satisfy the 10 CFR 54.4(a)(2) criterion and are in the scope of LR up to and including the first seismic restraint, which provide restraint in each of three orthogonal (X/Y/Z) directions beyond the nuclear safety related/NNS interface (safety class extension), or in limited instances to equivalent anchor (such as a wall penetration, large equipment connection or a series of supports).

NNS piping and tubing attached to nuclear safety related components are considered to meet the 10 CFR 54.4(a)(2) criterion up to a free end of NNS drain or vent piping: up to a flexible connection; between ends of nuclear safety related piping; and attached to large, floor mounted equipment as appropriate; or up to a transition from piping to ductwork. Only those safety class extensions that provide a boundary for scoping are of particular focus. Liquid filled piping downstream of the NNS piping included in a safety class extension satisfy the 10 CFR 54.4(a)(2) criterion for spatial interactions. Where the LR evaluation boundary of a system only extends up to a seismic (or equivalent) anchor, the extent of piping included in the scope of LR is determined.

Component supports in buildings and areas in the scope of LR, both Seismic Category II and non-seismic, are in the scope of LR as a bulk commodity that satisfies the 10 CFR 54.4(a)(2) criterion.

Potential for Spatial Interactions with Nuclear Safety Related SSCs

Spatial interactions can occur downstream of nuclear safety related/NNS interfaces or between nuclear safety related and NNS SSCs within the same vicinity. Spatial interactions may include physical impact, pipe whip, jet impingement, spray, flooding, or harsh environments such as caused by HELB. Spatial interactions may also include spray or leakage, such as caused by MELB/C or leakage from low energy SSCs.

A combination of mitigative and preventive options are used to determine which NNS systems or NNS portions of nuclear safety related systems and structures are in scope for 10 CFR 54.4(a)(2) due to the potential for spatial interaction. NNS protective (mitigative) features include structural commodities that have a credited function to protect nuclear safety related SSCs described in the FSAR and are in-scope per 10 CFR54.4(a)(2), as described above. Industry OE has shown that age-related pipe failures can and do occur at locations other than postulated locations. Therefore, the preventive option is also used to ensure the NNS piping and components with the potential for spatial interaction with nuclear safety related SSCs are included. The types of spatial interactions that satisfy the 10 CFR 54.4(a)(2) criterion are described further below.

Physical Impact

This category concerns potential spatial interaction of NNS SSCs falling on or otherwise physically impacting nuclear safety related SSCs such that safety functions may not be accomplished.

NNS overhead handling systems whose failure could result in damage to nuclear safety related SSCs that could prevent the accomplishment of a safety function are within the scope of LR based on the criterion of 10 CFR 54.4(a)(2).

Seismic Category II as well as other, non-seismic supports, enclosures (e.g., panels, cabinets, terminal/junction boxes), and miscellaneous structural components located in or, in the case of lines extending from the Seismic Category I Safeguards Building over the roof of the non-seismic Switchgear Building, adjacent to Seismic Category I structures are structural commodities that meet the 10 CFR 54.4(a)(2) criterion.

Flooding, Pipe Whip, Jet Impingement, or Harsh Environments

Dynamic effects associated with high-energy piping ruptures, HELBs at CPNPP are addressed in FSAR Section 3.6B. High-energy lines are listed in FSAR Table 3.6B-1 along with the pertinent FSAR Figure and Building. The buildings that house high-energy lines whose failure could impact nuclear safety related components include Auxiliary, Containment, Electrical and Control, and Safeguards Buildings. High energy lines located outdoors in the vicinity of these buildings are also included. The high-energy lines located in the non-seismic TB are attached to a Seismic Category I structure and also meet the 10 CFR 54.4(a)(2) criterion. It was shown by analysis to remain undamaged by the non-seismic building, structures, and components during a seismic event, as described in FSAR Section 3.7B.2.8.

High-energy systems are fluid systems that, during normal plant conditions, are either in operation or maintained pressurized under conditions where either or both of the following are met:

1. Maximum operating temperature exceeds (>) 200°F,

2. Maximum operating pressure exceeds (>) 275 pounds per square inch gauge (psig).

NNS portions of high-energy systems whose degradation could impact nuclear safety related component functions due to their location in or adjacent to Seismic Category I structures meet the 10 CFR 54.4(a)(2) criterion. Postulated break points and restraint locations are depicted in FSAR Figures. These figures do not postulate failure along the entire length or assume that a high-energy line does not fail. Therefore, the entire length of NNS high energy lines whose failure could impact nuclear safety related SSCs meet the 10 CFR 54.4(a)(2) criterion.

Spray or Leakage

Moderate and low energy systems have the potential for spatial interactions of spray and leakage (NEI 95-10 Appendix F). NNS systems and NNS portions of nuclear safety related systems with the potential for spray or leakage that could prevent nuclear safety related SSCs from performing their required safety function are in the scope of LR per 10 CFR 54.4(a)(2).

Low-energy systems are those standby, process, or drainage systems whose pressure is approximately atmospheric. Moderate-energy systems are fluid systems that, during normal plant conditions, are either in operation or maintained pressurized where both of the following are met:

1. Maximum operating temperature is 200°F or less (≤) and

2. Maximum operating pressure is above (>) atmospheric and is 275 psig or less (≤).

Components that do not contain liquids or steam cannot adversely affect nuclear safety related SSCs due to leakage or spray, as confirmed by OE. An NNS system or component containing only air or gas is not in the scope of LR based on the potential for spray or leakage but may be within scope if part of an NNS/nuclear safety related interface as described above.

Spaces approach to address potential spatial interactions

The review for potential age-related spatial interactions utilizes a “spaces” approach for license renewal scoping of liquid or steam-filled NNS systems or NNS portions of NSR systems with the potential for spatial interaction with NSR SSCs. This approach is consistent with other recent applicants for LR or subsequent license renewal (SLR) and focuses on the interaction between NNS and NSR SSCs that are located in the same space.

A "space" is defined as a room, cubicle or area that is separated from other spaces by substantial objects (such as wall, floors, or ceilings). Areas and rooms within the same building and elevation are considered a “space” unless it is verified that configuration and mitigative features are sufficient to limit communication between areas/rooms or to lower elevations via pipe routing, cable routing, vents, etc.

NNS systems or NNS portions of NSR systems that contain water, oil, or steam are located inside structures containing NSR SSCs. Some high-energy components adjacent to a Seismic Category I structure can potentially impact NSR SSCs in that structure. The FSAR indicates that NSR SSCs are Seismic Category I and located inside Seismic Category I structures. The Class 5 designation is assigned to NNS piping, plumbing, and process tubing located in Seismic Category I structures.

All Class 5 lines were evaluated for their capability to reduce the functioning of Seismic Category I systems and components. The focus of this evaluation was related to failure during a seismic event or high/moderate energy line break reducing the function of Seismic Category I systems and components to an unacceptable level.

Pertinent CLB documents address seismic considerations and pipe break postulations. NSR targets in these evaluations have been generally identified. However these targets do not constitute all NSR mechanical, EIC or structural SSCs in Seismic Category I structures or consider leakage onto a pipe or cable tray that communicates between areas, rooms, or elevations.

As such NNS systems and NNS portions of NSR systems that include Class 5 piping, tubing and in-line components, containing water, oil or steam meet the 10 CFR 54.4(a)(2) criterion for spatial interaction unless they are confirmed to have no potential for leakage or spray onto NSR SSCs. Notes are added to LRBDs in such instances.

Areas/rooms are generally defined by room number within the MEL. NNS systems or NNS portions of nuclear safety related systems are within scope per 10 CFR 54.4(a)(2), if fluid-filled portions of those systems are located within the same room, area or elevation or higher elevation as NSR components.

Although some MEL fields, in Maximo, are not verified/controlled, component location (room) is a design controlled field. The location of NNS fluid filled components and comparison to a search of safety class components in that location provides reasonable assurance of a potential for spatial interaction or lack thereof. If Maximo identifies NNS and NSR components in the same space, then the potential for spatial interaction exists.

Further determination relative to whether an NNS system or NNS portion of a nuclear safety related system is in scope based on spatial interaction is through review of FDs, and in certain instances architectural or area drawings or isometric drawings, as these documents show building/room boundaries. No credit was taken for separation by distance alone without a mitigative feature capable of preventing the spatial interaction. The mitigative features are included in the scope of license renewal. In addition, walkdowns are performed as warranted for confirmation of the determinations. However, these walkdowns and detailed reviews are limited to determining whether a mechanical system includes any components with a potential for spatial interaction with nuclear safety related SSCs.

Each CPNPP TB contains Class 1E cables. These cables are associated with instruments that actuate anticipatory reactor trip on turbine trip and are procured as Class 1E but are not NSR (FSAR Section 7.2.1.1.2 Item 6). GL 85-06 (Reference 1.7.34) states that the QA program for the NNS ATWS equipment does not need to meet the requirements of 10 CFR Part 50 Appendix B nor would compliance be judged in terms of the Appendix. Their function is anticipatory, not essential, and age related degradation of this redundant trip cannot prevent a reactor trip from occurring. No credit is taken in any of the FSAR safety analyses (Chapter 15) for this trip. Therefore, portions of NNS systems within the turbine building that could interact spatially with these Class 1E cables are not considered in scope per 10 CFR 54.4(a)(2), as spatial interaction will not prevent credited 10 CFR 54.4(a)(1) functions.

Structures within the scope of LR based on the criterion of 10 CFR 54.4(a)(1), Seismic Category I, provide support and protection to NSR equipment and are considered to meet the criterion of 10 CFR 54.4(a)(2) as support and protection is also provided for NNS components which prevent spatial interaction with nuclear safety related components.

2.1.5.3. Regulated Events – 10 CFR 54.4(a)(3)

The scope of LR includes those SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48), EQ (10 CFR 50.49), PTS (10 CFR 50.61), ATWS (10 CFR 50.62), and SBO (10 CFR 50.63). This section discusses the approach used to identify the systems and structures within the scope of LR based on this criterion. The systems and structures that perform intended functions in support of these regulated events are identified in the system/structure descriptions in Sections 2.3, 2.4, and 2.5.

Fire Protection

Criterion 10 CFR 54.4(a)(3) requires that all SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48) are included within the scope of LR.

The systems and structures required for the FP program to comply with the requirements of 10 CFR 50.48 include:

- Systems and structures required to demonstrate post-fire safe shutdown capabilities.
- Systems and structures required for fire detection and suppression.

- Systems and structures required to meet commitments made to Appendix A of Branch Technical Position (BTP) APCSB 9.5-1.

NRC guidance, including NUREG-0800 Section 9.5.1, Appendix B (Reference 1.7.35) states that the scope of 10 CFR 50.48 goes beyond the protection of nuclear safety related equipment, and also includes Fire Protection SSCs needed to minimize the effects of a fire and to prevent the release of radioactive material to the environment.

FSAR Section 9.5.1 references the FPR for the description of the Fire Protection Systems and Fire Protection program. The Fire Protection program has been developed to satisfy the requirements of 10 CFR Part 50 and BTP APCSB 9.5-1, Appendix A, and to meet Sections III.G, J, L or O of 10 CFR Part 50 Appendix R. Key sections of the FPR, detailing compliance with the subject requirements and forming the basis of the Fire Protection program, include the following:

- Section II, Fire Hazards Analysis Report
- Section III, Fire Safe Shutdown Analysis Report
- Section IV, FP Equipment/Systems Operational Administration
- Section V, Appendix C, Deviations

Section II of the FPR, Fire Hazards Analysis Report, contains the fire hazards analysis of CPNPP which includes a description by building of the: plant design, maximum permissible fire load, fire hazard classification, and FP and detection features. The impact of these factors on the fire safe shutdown equipment in the area and the overall effect on the plant's fire safe shutdown capability are also summarized.

Section III of the FPR, Fire Safe Shutdown Analysis Report, contains the fire safe shutdown assessment of CPNPP which includes a description of the design implementation and a list of the fire safe shutdown systems and components.

Section IV of the FPR, FP Equipment/Systems Operational Administration, contains the FP program administrative control requirements for the FPSs and equipment at CPNPP, which includes a description of the operability, testing, and surveillance requirements.

Section V, Appendix C of the FPR, Deviations, lists the deviations to Appendix R and exemptions from BTP APCSB 9.5-1, Appendix A.

Based on the review of the CPNPP current licensing bases for FP, systems were determined to be in the scope of LR on the basis of their support of 10 CFR 50.48 requirements. Section 2.3 contains the results of the review of the CPNPP passive mechanical components that support at least one of the following required functions:

- required to function to supply fire suppression in accordance with BTP APCSB 9.5-1, Appendix A, and 10 CFR 50.48, including 10 CFR Part 50 Appendix R (such as FPS);

- required to meet the guidance in 10 CFR Part 50, Appendix R, Section III.G, J, L, or O; or

- required to meet the guidance in GLs 81-12 (Reference 1.7.36) and 86-10.

Structures providing support, shelter, or protection to equipment meeting the criterion of 10 CFR 54.4(a)(3) based on the requirements of 10 CFR 50.48 are within the scope of LR based on 10 CFR 54.4(a)(3). Section 2.4 contains the results of the review for the CPNPP structures and structural components that provide support, shelter, protection, or fire protection.

As described in Section 2.1.1, a bounding approach to scoping is used for EIC systems. All EIC Systems (except Meteorological Instrumentation and Security Systems) are automatically considered within the scope of LR. Additionally, all EIC components that are contained within mechanical systems are automatically within scope, regardless of whether the mechanical system is included within scope. Consequently, EIC components that support the requirements of 10 CFR 50.48 are included within the scope of LR.

Environmental Qualification

Criterion 10 CFR 54.4(a)(3) requires that all SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49) be included within the scope of LR.

As described in the CPNPP Seismic and EQ administrative procedure, equipment located in a potentially harsh environment that is Class 1E equipment, certain non-class 1E, electrical equipment, and certain Non 1E RG 1.97 (Reference 1.7.37) instrumentation which are required to function during or following the DBEs are subject to EQ. The CPNPP Maximo Equipment List administrative procedure controls the maintenance of the list of EQ components contained within the MEL. Components identified as EQ in the MEL satisfy the 10 CFR 54.4(a)(3) criterion and are included within the scope of LR.

As described in Section 2.1.1, a bounding approach to scoping is used for EIC systems. All EIC Systems (except Meteorological Instrumentation and Security Systems) are automatically considered within the scope of LR. Additionally, all EIC components that are contained within mechanical systems are automatically within scope, regardless of whether the mechanical system is included within scope. Consequently, EIC components that support the requirements of 10 CFR 50.49 are included within the scope of LR.

Indication of which mechanical systems include EQ components is provided in Section 2.3.

Structures providing support, shelter or protection to equipment meeting the criterion of 10 CFR 54.4(a)(3) based on the requirements of 10 CFR 50.49 are within the scope of LR based on 10 CFR 54.4(a)(3). Section 2.4 contains the results of the scoping and screening review for the CPNPP structures.

Pressurized Thermal Shock

Criterion 10 CFR 54.4(a)(3) requires that all SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the

Commission's regulations for PTS (10 CFR 50.61) be included within the scope of LR.

PTS is a potential PWR event or transient causing vessel failure due to severe overcooling (thermal shock) concurrent with, or followed by, significant pressure in the reactor vessel (RV). The requirements in 10 CFR 50.61 include specific operational limits for PTS pertaining to the belt-line region of the RV.

The only system currently relied upon to meet the PTS regulation is the reactor coolant system (RCS), which contains the RV. There are no electrical systems or structures relied upon to meet the PTS regulation.

Structures providing support, shelter or protection to equipment meeting the criterion of 10 CFR 54.4(a)(3) based on the requirements of 10 CFR 50.61 are within the scope of LR based on 10 CFR 54.4(a)(3). Section 2.4 contains the results of the scoping review for the CPNPP structures.

Anticipated Transient Without Scram

Criterion 10 CFR 54.4(a)(3) requires that all SSCs relied on in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for ATWS (10 CFR 50.62) be included within the scope of LR.

An ATWS is a postulated operational transient that generates an automatic scram signal, accompanied by a failure of the reactor protection system to automatically shut down the reactor. The ATWS rule (10 CFR 50.62) requires improvements in the design and operation of light-water cooled water reactors to reduce the likelihood of failure to automatically shut down the reactor following anticipated transients, and to mitigate the consequences of an ATWS event.

In response to NRC requirements, CPNPP Unit 1 and Unit 2 include ATWS mitigation system actuation circuitry (AMSAC), described in Section 7.8 of the FSAR. The AMSAC System for each unit provides backup to the Reactor Trip System (RTS) and Engineered Safety Features (ESF) Actuation System (ESFAS) for initiating turbine trip and auxiliary feedwater flow in the event of an anticipated transient. The AMSAC System is independent of and diverse from the RTS and the ESFAS with the exception of the analog SG level and turbine first stage pressure inputs, and the final actuation devices. It is a highly reliable, microprocessor-based, non-safety related circuitry system.

Because the AMSAC System uses existing sensors and actuation devices that are not unique to the ATWS function, no mechanical systems include components credited for ATWS. Note that AMSAC consists of different CPNPP electrical systems and is not a standalone EIC system.

Structures providing support, shelter or protection to equipment meeting the criterion of 10 CFR 54.4(a)(3) based on the requirements of 10 CFR 50.62 are within the scope of LR based on 10 CFR 54.4(a)(3). Section 2.4 contains the results of the scoping review for the CPNPP structures.

As described in Section 2.1.1, a bounding approach to scoping is used for EIC systems. All EIC Systems (except Meteorological Instrumentation and Security Systems) are automatically considered within the scope of LR. Additionally, all EIC components that are contained within mechanical systems are automatically within scope, regardless of whether the mechanical system is included within scope. Consequently, EIC components that support the requirements of 10 CFR 50.62 are included within the scope of LR.

Station Blackout

Criterion 10 CFR 54.4(a)(3) requires that all SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63) be included within the scope of LR.

A SBO event is a complete loss of alternating current (AC) electric power to the essential and nonessential switchgear buses in a nuclear power plant (i.e., loss of the offsite electric power system concurrent with generator trip and unavailability of the onsite emergency AC power sources). SBO does not include the loss of available AC power to buses fed by station batteries through inverters or by alternate AC sources, nor does it assume a concurrent single failure or design basis accident (DBA). The objective of this requirement is to assure that nuclear power plants are capable of withstanding a SBO and maintaining adequate reactor core cooling and appropriate containment integrity for a required duration.

CPNPP capabilities, commitments and analyses that demonstrate compliance with 10 CFR 50.63 are documented in NRC SERs and correspondence related to the SBO rule, as well as the SBO DBD. CPNPP has developed a four-hour AC independent coping approach to address the requirements of 10 CFR 50.63; however, credit is taken for the operation of selected nuclear safety related systems which are common to Units 1 and 2.

Based on the CPNPP current licensing bases for SBO, systems were determined to be in the scope of LR on the basis of their support of 10 CFR 50.63 requirements. Section 2.3 identifies the CPNPP mechanical systems that contain mechanical components that support SBO requirements.

Based on the current licensing bases for SBO, system intended functions performed in support of 10 CFR 50.63 requirements were determined. Individual system scoping evaluations in Section 2.3 contain the results of the review for CPNPP mechanical systems.

NUREG-1800 and NRC staff guidance on scoping of equipment relied on to meet the requirements of the SBO rule (10 CFR 50.63) for LR has been incorporated into the CPNPP scoping methodology. In accordance with NUREG-1800, the SSCs required to cope with a SBO event are included within the scope of LR. Upon loss of all offsite AC power, station standby power sources, consisting of four onsite diesel generators (DGs) (two per unit) are provided to satisfy the loading requirements of the AC nuclear safety related loads at CPNPP. System redundancy precludes loss of all onsite power as a result of any single failure. The 138 kV switchyard is the preferred source of offsite power for restoration of offsite power following a SBO event. Startup transformer XST1 and alternate startup transformer XST1A are connected to a common overhead line from the 138 kV switchyard. This power path includes power out to the first set of switchyard breakers in the 138 kV switchyard. Transformer XST1 is connected to the nuclear safety related 6.9 kV safeguard buses of each unit. Transformer XST1A serves as an alternate transformer in this power path. The 345 kV switchyard is the back-up source of offsite power for restoration of offsite power following a SBO event when the 138 kV switchyard is unavailable. Startup transformer XST2 and alternate startup transformer XST2A are connected to a common overhead line from the 345 kV switchyard. This power path includes power out to the first set of switchyard breakers in the 345 kV switchyard. Transformer XST2 is also connected to the nuclear safety related 6.9 kV safeguard buses of each unit. Transformer XST2A serves as an alternate transformer in this power path. There are no interconnections between the 138 kV switchyard and the 345 kV switchyard at the CPNPP site. The 138 kV switchyard is physically and electrically independent of the 345 kV switchyard.

Figure 2.5-1 identifies the major components or commodities associated with restoration of offsite power following a SBO event.

Structures providing support, shelter or protection to equipment meeting the criterion of 10 CFR 54.4(a)(3) based on the requirements of 10 CFR 50.63 are within the scope of LR based on 10 CFR 54.4(a)(3). Section 2.4 contains the results of the scoping review for the CPNPP structures.

As described in Section 2.1.1, a bounding approach to scoping is used for EIC systems. All EIC Systems (except Meteorological Instrumentation and Security Systems) are automatically considered within the scope of LR. Additionally, all EIC components that are contained within mechanical systems are automatically within scope, regardless of whether the mechanical system is included within scope. Consequently, EIC components that support the requirements of 10 CFR 50.63 are included within the scope of LR.

2.1.5.4. System and Structure Intended Functions

For the systems and structures within the scope of LR, the intended functions that are the bases for including them within scope are identified and documented in the scoping evaluation. The system and structure intended functions are based on the applicable CLB and other reference documents or drawings. The component level intended functions are the passive component functions that are necessary to support the system or structure intended functions. The structure and component intended functions are further described in Section 2.1.6.2.

2.1.5.5. Scoping Boundary Determination

Systems and structures that are included within the scope of LR are further evaluated to determine the population of in scope mechanical and structural components. This part is also a transition from the scoping process to the screening process. Mechanical systems are depicted primarily on the FDs that show the system components and their functional relationships, while structures are depicted on physical drawings. All EIC systems and components (except Meteorological Instrumentation and Security Systems) are in-scope and are placed into commodity groups and are evaluated as commodities. Scoping boundaries for mechanical systems, structures, and EIC are, therefore, described separately.

Mechanical Systems

For mechanical systems, mechanical components that support the system intended functions are included within the scope of LR and are depicted on the applicable system FDs. Mechanical system FDs were highlighted to create LR boundary drawings (LRBDs) showing the in-scope components that are subject to AMR. Components that are required to support a nuclear safety related function, or a function that demonstrates compliance with one of the LR regulated events, are identified on the LRBDs by green highlighting, and in the case of components in the reactor coolant pressure boundary (RCPB), by blue highlighting. NNS components that are connected to nuclear safety related components and are required to provide structural support at the nuclear safety related/NNS interface, non-commodity NNS components with a credited NNS function, and NNS components whose failure could prevent satisfactory accomplishment of a nuclear safety related function due to spatial interaction with nuclear safety related SSCs are identified on the LRBDs by magenta highlighting. A computer sort and download of associated system components from the CPNPP MEL confirms the scope of components in the system. Mechanical system boundaries are further discussed in Section 2.1.6.1 below.

Structures

For structures, the structural components that are required to support the intended function(s), as described in the CLB, are included within the scope of LR. The structural components are identified from a review of applicable information sources in Section 2.1.2 which includes plant design drawings of the structure. Component listings from the CPNPP MEL were reviewed to determine structure level intended functions. Structural components such as structural bolting required to support the structure proper are evaluated with the structure. Structural bolting supporting the intended function of a component support, or a bulk commodity is evaluated with the component support or bulk commodity. A site plan layout drawing is highlighted for CPNPP to create an LRBD showing the structures within the scope of LR. Structural boundaries are further discussed in Section 2.1.6.1 below.

Electrical

EIC systems and components within mechanical systems, did not require further system evaluations to determine which components were required to perform or support the identified intended functions. A bounding scoping approach is used for electrical equipment. Under this approach, all electrical components were included within the scope of LR. This bounding approach is consistent with the electrical scoping results for previous LRAs, as well as approved SLRAs. In scope electrical components were placed into commodity groups and then evaluated as commodities during the screening process as described in Section 2.1.6.1 below.

2.1.6. SCREENING PROCEDURE

Once the SSCs within the scope of LR have been determined, the next step is to determine which structures and components are subject to an AMR.

2.1.6.1. Identification of Structures and Components Subject to AMR

The requirement to identify structures and components subject to AMR is specified in 10 CFR 54.21, which states:

Each application must contain the following information:

(a) An integrated plant assessment (IPA). The IPA must:

(1) For those SSCs within the scope of this part, as delineated in 10 CFR 54.4, identify and list those structures and components subject to an AMR. Structures and components subject to an AMR shall encompass those structures and components--

(i) That perform an intended function, as described in Sec. 54.4, without moving parts or without a change in configuration or properties. These structures and components include, but are not limited to, the reactor vessel, the reactor coolant system pressure boundary, steam generators, the pressurizer, piping, pump casings, valve bodies, the core shroud, component supports, pressure retaining boundaries, heat exchangers, ventilation ducts, the containment, the containment liner, electrical and mechanical penetrations, equipment hatches, seismic Category I structures, electrical cables and connections, cable trays, and electrical cabinets, excluding, but not limited to, pumps (except casing), valves (except body), motors, diesel generators, air compressors, snubbers, the control rod drive, ventilation dampers, pressure transmitters, pressure indicators, water level indicators, switchgears, cooling fans, transistors, batteries, breakers, relays, switches, power inverters, circuit boards, battery chargers, and power supplies; and

(ii) That are not subject to replacement based on a qualified life or specified time period.

(2) Describe and justify the methods used in paragraph (a)(1) of this section.

Structures and components that perform an intended function without moving parts or without change in configuration or properties are defined as passive for LR. Passive structures and components that are not subject to replacement based on a qualified life or specified time period are defined as long-lived for LR. The screening process is used to identify passive, long-lived structures, and components within the scope of LR that are subject to AMR.

NUREG-1800, “Standard Review Plan for Review of License Renewal Applications for Nuclear Power Plants” and NEI 95-10, Industry Guidelines for Implementing the Requirements of 10 CFR 54 – The License Renewal Rule, Appendix B provide guidance for the identification of passive structures and components and on the exclusion of active components from AMR. Components, or assemblies, that perform their function with moving parts or a change in configuration or properties which includes a ‘change of state’ are active and are not subject to AMR. Most passive structures and components are long-lived. If a passive component is determined not to be long-lived, such a determination is documented within the screening evaluation.

The CPNPP structures and components subject to AMR have been identified in accordance with the requirements of 10 CFR 54.21 described above. The process and methodology to meet these requirements for mechanical systems, structures, and electrical commodities is described as follows:

Mechanical Systems

The mechanical systems screening process began with the results from the scoping process. For in-scope mechanical systems, system FDs were highlighted to create LRBDs. These LRBDs were reviewed to identify passive, long-lived components subject to AMR. Component listings from the MEL were also reviewed to confirm that all system components were considered. Plant walkdowns were performed when required for confirmation. Finally, the identified list of passive, long-lived system components was benchmarked against previous LRAs, as well as approved SLRAs, containing similar systems.

Some mechanical components, when combined, are considered a complex assembly. A complex assembly is a predominately active component where the performance of its components is closely linked to that of the intended function of the entire assembly, such that testing and monitoring of the assembly is sufficient to identify degradation of these components. Examples of complex assemblies include diesel engines, instrument air compressors, and chiller units. Complex assemblies are considered active and can be excluded from the requirements of AMR. However, to the extent that complex assemblies include piping or components that interface with external equipment, or components that cannot be adequately tested or monitored as part of the complex assembly, those components are identified and subject to AMR. This follows the screening methodology for complex assemblies as described in Table 2.1-2 of NUREG-1800.

Mechanical components are screened with the system in which they are scoped (assigned in MEL and shown on FDs). The CPNPP system boundaries, are shown on FDs by system breaks or component location number (first two alphabetic characters designate the assigned system) and are carried forward to the IPA evaluations and LRBDs. Related systems are grouped as appropriate for evaluation. For example, a) ASME Class 1 portions of the Chemical and Volume Control, Residual Heat Removal (RHR), and Safety Injection Systems are addressed with the RCS, b) Boron Recycle and Boron Thermal Regeneration Systems are addressed with the related Chemical and Volume Control System (CVCS), c) ventilation and cooling systems are addressed together, and d) Breathing Air, Instrument Air, Service Air and Plant Gas (Nitrogen Supply) systems are evaluated together.

Structures

The structure screening process also began with the results from the scoping process. If only selected portions of a structure are in scope, the in-scope portions are described in the scoping evaluation. The associated structure drawings were reviewed to identify the passive, long-lived structures, and components. Plant walkdowns were performed when required for confirmation. Finally, the identified list of passive, long-lived structures and components was benchmarked against previous LRAs, as well as approved SLRAs.

Electrical Commodities

The screening of EIC components in EIC and mechanical systems used a bounding approach as described in NEI 95-10. EIC components for in-scope systems were assigned to commodity groups consistent with Table 2.1-5 of NUREG-1800. The commodities subject to an AMR were identified by applying the “passive” screening criteria of 10 CFR 54.21(a)(1). This method provides the most efficient means for determining the electrical commodities subject to an AMR since many EIC components and commodities are active. Active components and commodities may be eliminated from AMR per 10 CFR 54.21(a)(1).

The sequence of steps and special considerations for identification of electrical commodities that require an AMR is as follows:

1. EIC components and commodities in systems within the scope of LR at CPNPP were identified and listed. The listing provided in Table 2.1-5 of NUREG-1800, is the basis for this list. EIC components and commodities were organized into groups such as circuit breakers, switches, and cables. Individual specific components were not identified.

2. Following the identification of the electrical commodities, the criterion of 10 CFR 54.21(a)(1)(i) was applied to identify commodities that perform their functions without moving parts or without a change in configuration or properties (referred to as “passive” components). These commodities were identified utilizing the guidance of NEI 95-10 and Table 2.1-5 of NUREG-1800.

3. The screening criterion found in 10 CFR 54.21(a)(1)(ii) excludes those commodities that are subject to replacement based on a qualified life or specific time period from the requirements of an AMR. The 10 CFR 54.21(a)(1)(ii) screening criterion was applied to those commodities that were not previously eliminated by the application of the 10 CFR 54.21(a)(1)(i) screening criterion. Components and commodities included in the plant Environmental Equipment Qualification (EEQ) AMP are replaced on a specified interval based on a qualified life. Components and commodities in the Environmental Qualification of Electric Components (B.2.2.2) AMP do not meet the “long-lived” criterion of 10 CFR 54.21(a)(1)(ii) and are considered “short-lived” per the regulatory definition and are, therefore, not subject to an AMR.

4. EIC components and commodities were not evaluated to determine if they perform a LR intended function during the scoping of systems. At this point in the screening process, the remaining passive electrical commodities are reviewed to determine if the commodity performs a LR intended function. If

an electrical commodity does not perform a LR intended function, it is not considered further and, therefore, is not subject to an AMR.

5. Components and commodities which support or interface with electrical components and commodities (for example, cable trays, conduits, instrument racks, panels, and enclosures) are evaluated as structural components in Section 2.4.

The electrical commodities that require an AMR are the separate electrical commodities that are not a part of a larger active component. The passive commodities that are not subject to replacement based on a qualified life or specified time period are subject to an AMR. For CPNPP, the electrical commodities that require an AMR are identified in Section 2.5.

EIC components whose primary function is electrical can also have a mechanical pressure boundary function. These components include elements, resistance temperature detectors (RTDs), sensors, thermocouples, transducers, and electric heaters. According to Appendix B of NEI 95-10, the electrical portions of these components are active per 10 CFR 54.21(a)(1)(i) and are therefore not subject to AMR. Only the pressure boundary of such an in-scope component is subject to AMR, and the pressure boundary function for these EIC components is addressed in the mechanical review.

2.1.6.2. Intended Function Definitions

The intended functions that the components and structures must fulfill are those functions that are the bases for including them within the scope of LR. A component intended function is defined as a passive component function that must be performed in order for the system or structure to be able to perform the system or structure intended function(s). For example, pressure boundary failure of a component would cause loss of inventory from the system, and the system would subsequently be unable to perform its intended function(s). Structures and components may have multiple intended functions. CPNPP has considered multiple intended functions where applicable, consistent with the staff guidance provided in Table 2.1-3, 2.1-4(a), and 2.1-4(b) of NUREG-1800 Revision 2.

Table 2.1-1 provides expanded definitions of structure and component passive intended functions identified in this application.

Table 2.1-1
Structure and Component Intended Functions

Intended Function	Definition
Absorb neutrons	Absorb neutrons.
Diaphragm integrity	Maintain integrity of diaphragm to prevent interference with a nuclear safety related component function.
Direct flow	Provide spray shield or curbs for directing flow or provide means of fluid flow diversion within a component (as seen in divider plates, heat exchanger coil shields, vortex diffusers, etc.).

Table 2.1-1
Structure and Component Intended Functions

Intended Function	Definition
Electrical continuity	Provide electrical connections to specified sections of an electrical circuit to deliver voltage, current or signals.
Filter	Provide filtration.
Fire barrier	Provide rated fire barrier to confine or retard a fire from spreading between adjacent areas of the plant.
Flood barrier	Provide flood protection barrier for internal or external flooding.
Flow distribution	Maintain flow distribution.
Heat sink	Provide heat sink during SBO or design basis accidents.
Heat transfer	Provide heat transfer.
HELB shielding	Provide shielding against HELBs.
Insulate (electrical)	Insulate and support an electrical conductor.
Leakage boundary (spatial)	NNS components that maintain mechanical and structural integrity to prevent spatial interactions that could cause failure of nuclear safety related SSCs.
Limit leakage	Maintain leakage within acceptable levels.
Maintain adhesion	Provides adhesion to the substrate.
Missile barrier	Provide missile barrier (internally or externally generated).
Mechanical closure	Provide closure of components. Typically used with bolting.
Pipe whip restraint	Provide pipe whip restraint.
Pressure boundary	Provide pressure-retaining boundary or essentially leak tight barrier so that sufficient flow at adequate pressure is delivered, or provide fission product barrier for containment pressure boundary, or provide containment isolation for fission product retention.
Pressure relief	Provide over-pressure protection.
Shelter, protection	Provide shelter/protection for structures and components.
Shielding	Provide shielding against radiation.
Spray	Convert fluid into spray.
Structural integrity (attached)	NNS components that maintains mechanical and structural integrity to provide structural support to attached nuclear safety related SSCs.
Structural support	Provide structural and/or functional support to nuclear safety related and/or NNS SSCs.
Thermal insulation	Control of heat loss to preclude overheating of nearby nuclear safety related SSCs.
Thermal insulation jacket integrity	Prevent moisture absorption and provide physical support of thermal insulation.
Throttle	Provide flow restriction.
Water retaining boundary	Provide an essentially leak-tight boundary.

Table 2.1-1
Structure and Component Intended Functions

Intended Function	Definition
Withstand thermal stresses	Operate without loss or degradation of function as designed within installed environment.

2.1.6.3. Stored Equipment

In the event of a fire, repairs are allowed in order to perform the transition from hot standby to cold shutdown and to maintain cold shutdown. Repair activities include replacement of damaged components to restore operability of equipment and fuse removal and replacement for a control circuit to recover from the effects of a fire. Stored components that are replaced in the event a repair is needed, as described in the CPNPP FPR, following a fire are within the scope of LR. The tools needed to complete these repairs are not in the scope of LR.

The nuclear safety related Fuel Building (FB) Wonderhoist Crane is within the scope of LR and is addressed in Section 2.4. It is stored in the warehouse when not in use. This crane performs its nuclear safety related function within the FB where it handles the SFP swing gates. The warehouse which stores this crane is not considered within the scope of LR. The crane performs no nuclear safety related functions while stored in the warehouse and is inspected prior to use within the FB.

Note: As scoping is performed at the system and structure level, determination of stored equipment is performed during screening to determine which components within the system/structure are subject to AMR.

2.1.6.4. Abandoned Components

Abandoned equipment that has not been verified to be permanently isolated, e.g., lines cut and capped, leads lifted and drained that is located in a space with nuclear safety related equipment is included within the scope of LR in accordance with 10 CFR 54.4(a)(2). The abandoned equipment in the scope of LR was determined from discussions with site personnel and from reviews of the site MEL and relevant documents, such as design change notices, system and structure scoping results, and FDs that denote abandoned equipment using hash marks and notes. The abandoned equipment includes:

- The Electric Hydrogen Recombiners are abandoned in place (FSAR 6.2.5.1.2, 6.2.5.2.1, 6.2.5.3.3). These abandoned components do not contain a liquid or perform a nuclear safety related function and are not credited for a regulated event. The potential for a component within this system to impact a nuclear safety related component through spatial interaction is evaluated in Section 2.3.2.1.

- Boron Concentration Measurement System is abandoned in place (FSAR 7.7.1.10, 9.3.4.1.21). This abandoned system and associated components do not perform a nuclear safety related function and is not credited for a regulated event. The potential for a component within this system to impact a nuclear safety related component through spatial interaction is evaluated in Section 2.3.3.1.

- The jockey fire pump and diesel driven fire pump located in the SWIS have been abandoned in place (FSAR 9.2.1.10.1, Table 8.3-11). Fire protection requirements are met by the fire pumps located in the Fire Pump House. The potential for these NNS components to impact a nuclear safety related function is addressed in the FPS screening evaluation in Section 2.3.3.7.

- The Reverse Osmosis System portion of the Liquid Waste Processing System is not used at CPNPP and many of the systems associated components have been abandoned in place (FSAR 11.2.2.4.2). This system and associated components do not perform a nuclear safety related function and are not credited for a regulated event. The potential for any component, including abandoned components, within this system to impact a nuclear safety related component is evaluated during screening as part of the Liquid Waste Processing System in Section 2.3.3.14.

- The Waste Baling System is part of the Solid Waste Management System. The waste baler located inside the Unit 1 RCB is abandoned in place (FSAR 11.4). This portion of the system and associated components do not perform a nuclear safety related function and are not credited for a regulated event. The potential for any component, including abandoned components, within this system to impact a nuclear safety related component is evaluated in Section 2.3.3.14 as part of the Solid Waste Management System. Note that the Waste Baling System within the FB has not been abandoned.

- Portions of the Potable and Sanitary Water System (PW) are abandoned in place and no longer used (FSAR Table 17A-1, Potable Water System Flow Diagrams). This system and associated components do not perform a nuclear safety related function and are not credited for a regulated event. The potential for any component, including abandoned components, within this system to impact a nuclear safety related component is evaluated in Section 2.3.3.9 as part of the Potable and Sanitary Water System.

- Some exhaust dampers considered to be part of the Safeguards Building (SGB) Ventilation system are abandoned in place in the open position (FSAR 9.4.5.3). These exhaust dampers are evaluated in Section 2.3.3.8 as part of the Primary Plant Ventilation System.

- The Chemical Feed System for the Unit 1 SGs was removed from service when the new SGs were installed. The remaining Unit 1 chemical feed recirculation components (i.e., pumps, piping, pipe supports, and instrumentation) have been disconnected, capped, and abandoned in place. The ability of these recirculation lines to impact a nuclear safety related function through spatial interaction is addressed in the Chemical Feed System screening evaluation in Section 2.3.4.4.

Note: As scoping is performed at the system and structure level, determination of abandoned equipment is performed during screening along with system LR boundary determination.

2.1.6.5. Consumables

The evaluation process for consumables is consistent with the guidance provided in NUREG-1800, Table 2.1-3. Consumables have been divided into the following four (4) groups for the purpose of LR: (a) packing, gaskets, component seals, and O-rings; (b) structural sealants; (c) oil, grease, and component filters; and (d) system filters, fire extinguishers, fire hoses, and air packs.

- Group (a) subcomponents (packing, gaskets, component seals, and O-rings): Based on ANSI B31.1 and the American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel (B&PV) Code Section III, the subcomponents of pressure retaining components are not pressure-retaining parts. Therefore, these subcomponents are not relied on to perform a pressure-retaining function and are not subject to AMR.

- Group (b) structural sealants: Structural sealants are within the scope of LR and are reviewed in structural Section 3.5.

- Group (c) subcomponents (oil, grease, and component filters): These subcomponents are short-lived and are periodically replaced. Various plant procedures are used in the replacement of oil, grease, and filters in components that are in scope for LR. Therefore, these subcomponents are not subject to an AMR.

- Group (d) consumables (system filters, fire extinguishers, fire hoses, and air packs): System Ventilation filters are replaced in accordance with plant procedures based on vendor manufacturers' requirements and system testing. Fire extinguishers, self-contained breathing apparatuses, and fire hoses are within the scope of LR but are not subject to aging management because they are replaced based on condition. These components are periodically inspected in accordance with National Fire Protection Association (NFPA) standards. These standards require replacement of equipment based on their condition or performance during testing and inspection. Other equipment such as portable fans and smoke exhausters are periodically inspected for condition and replaced if warranted. These components are not long-lived and are subject to replacement based on NFPA standards; therefore, an AMR is not required.

2.1.7. GENERIC SAFETY ISSUES

In accordance with the guidance in NEI 95-10 and Appendix A.3 of NUREG 1800, review of NRC generic safety issues (GSIs) as part of the LR process is required to satisfy 10 CFR 54.29.

GSIs designated as active or unresolved in NUREG-0933, Appendix B (Reference 1.7.38), that involve aging effects for structures and components subject to an AMR or TLAA evaluations are to be addressed in the LRA. GSIs designated as active or unresolved were reviewed to determine if they involve aging effects for structures and components subject to an AMR or time-limited aging analysis evaluations.

2.1.7.1. GSI-163

GSI-163, Multiple Steam Generator Tube Leakage, has been incorporated into the CPNPP Steam Generator Program. The issue involves inspection requirements for SG tubes, which are addressed in Appendix B, Section B.2.3.10.

2.1.7.2. GSI-186

GSI-186, Potential Risk and Consequences of Heavy Load Drops in Nuclear Power Plants, involves issues related to crane design and operation. Aging effects are not central to these issues. The issue does not involve TLAA evaluations, including typical crane related TLAAs such as cyclic loading analyses. However, crane rails, bridges, etc. for cranes and hoists with the potential for heavy load drops are in the scope of LR and are subject to AMR as described in Section 2.4.14.

2.1.7.3. GSI-189

GSI-189, Susceptibility of Ice Condenser and Mark III containments to Early Failure from Hydrogen Combustion During a Severe Accident, required PWR ice condensers and boiling water reactor (BWR) Mark IIIs designed containments to be equipped with a supplemental hydrogen control system to deal with large quantities of hydrogen for postulated recoverable degraded core events. This issue is not applicable to CPNPP.

2.1.7.4. GSI-190

GSI-190, Fatigue Evaluation of Metal Components for 60-year Plant Life, concluded that licensees should address the effects of reactor coolant environment on component fatigue life as AMPs are formulated in support of LR. Accordingly, the issue of environmental effects on component fatigue life is addressed in Section 4.3.4.

2.1.7.5. GSI-191

GSI-191, Assessment of Debris Accumulation on PWR Sump Performance, addresses the potential for blockage of containment sump strainers that filter debris from cooling water supplied to the safety injection (SI) and containment spray pumps following a postulated loss of coolant accident (LOCA). The issue is based on the identification of new potential sources of debris, including failed containment coatings, which may block the sump strainers. Containment coatings are addressed in Section 2.4.1, Section 4.7.6, and in Appendix B, Section B.2.3.36.

2.1.7.6. GSI-193

GSI-193, BWR Emergency Core Cooling Systems (ECCS) Suction Concerns, addresses the possible failure of low pressure ECCS due to unanticipated, large quantities of entrained gas in the suction piping from suppression pools in BWR Mark I containments. This issue is not applicable to CPNPP.

2.1.7.7. GSI-196

GSI-196, Boral Degradation, addresses the potential for spent fuel racks using BORAL for neutron absorption experiencing problems with swelling and degradation of the BORAL plates over long periods of time. This is addressed in Appendix B, Section B.2.3.26.

2.1.7.8. GSI-199

GSI-199, Implications of Updated Probabilistic Seismic Hazard Estimates in Central and Eastern United States on Existing Plants, addresses how current estimates of the seismic hazard level at some nuclear sites in the central and eastern United States might be higher than the values used in their original designs and previous evaluations. The issue does not involve TLAA evaluations or aging effects.

2.1.7.9. GSI-204

GSI-204, Flooding of Nuclear Power Plant Sites Following Upstream Dam Failure, relates to potential flooding effects from upstream dam failure on nuclear power plant sites, SFPs, and sites undergoing decommissioning with spent fuel stored in SFPs. The issue does not involve TLAA evaluations. However, barriers to external and internal flooding are in the scope of LR and subject to AMR, as described in Section 2.4.

2.2. PLANT LEVEL SCOPING RESULTS

Table 2.2-1
Plant Level Scoping Results: Mechanical Systems

LRA System Name	CPNPP System Name	In Scope for LR	Sections
Reactor Vessel, Internals, and Reactor Coolant System

1 Includes the (accessible) Service Water Tunnel and SFP as rooms/areas.
2 FWST itself is addressed in Section 2.3.3.7.
3 Missile-protected, concrete Tanks with the stainless steel liners addressed in Sections 2.3.2.3, 2.3.3.4, and 2.3.4.1, respectively. Connected tunnels are accessible and considered as another room/area in the Safeguards Buildings.
4 Located inside the Protected Area (PA) a significant distance from Seismic Category I structures.
5 Located inside the PA in the vicinity of Seismic Category I structures, house only NNS components, and failure does not impact Seismic Category I structures.
6 Water control or related structures that are separated from Seismic Category I structures by a great distance and have no interaction with nuclear safety related components or the nuclear safety related SSI. Service Water Chlorination Building adjacent to the SWIS has been found to have no potential to impact the SWIS or nuclear safety related SSCs in it (Section 2.4.8).

2.3. SCOPING AND SCREENING RESULTS: MECHANICAL SYSTEMS

The scoping and screening results for mechanical systems consist of components and component groups subject to AMR, which are then grouped and presented on a system basis. Brief descriptions of mechanical systems within the scope of LR are provided as background information. Mechanical system intended functions are provided for in-scope systems. For each in-scope system, components or component groups requiring AMR are provided. For the sections where the system description applies to the system on each Unit, a statement is included indicating that the systems for Units 1 and 2 are essentially identical. The word “essentially” is utilized to clarify that there may be minor differences between the systems on each Unit (e.g., valve numbering, locations of vents and drains, etc.), but these differences would not affect the information that follows.

The mechanical scoping and screening results are provided in four sections:

- Reactor Vessel, Internals, and Reactor Coolant System (2.3.1)
- Engineered Safety Features (2.3.2)
- Auxiliary Systems (2.3.3)
- Steam and Power Conversion Systems (2.3.4)

2.3.1. <u>Reactor Vessel, Internals, and Reactor Coolant System</u>

The following systems are addressed in this section:

- Reactor Vessel (2.3.1.1)
- Reactor Vessel Internals (2.3.1.2)
- Reactor Coolant System and Attached Piping (2.3.1.3)
- Steam Generators (2.3.1.4)

2.3.1.1. <u>Reactor Vessel</u>

<u>Description</u>

The reactor pressure vessel (RPV) is cylindrical, with a welded hemispherical bottom head and a removable, flanged and gasketed, hemispherical upper head. The vessel contains the core, core supporting structures, control rods and other parts directly associated with the core.

The purpose of the RPV is to maintain the RCPB and provide structural support for the RVI, nuclear fuel, incore instrumentation, and control rod drive (CRD) mechanisms (CRDMs).

The RPV accomplishes the specified purpose by providing a RCPB for the circulation of fluid from the RCS and by providing structural support for the RVI, incore instrumentation, and CRDMs during normal operations and DBEs. The vessel has inlet and outlet nozzles located in a horizontal plane just below the RV flange but above the top of the core. Coolant enters the vessel through the inlet nozzles and flows down the core barrel-vessel wall annulus, turns at the bottom, and flows up through the core to the outlet nozzles.

The RV is composed of the closure head, CRDM assembly, nozzles, safe ends and welds, vessel external attachments, vessel internal attachments, vessel shell, bottom head, and bottom mounted instruments. All pressure-containing surfaces in contact with the reactor water are stainless steel clad.

The vessel closure head is attached to the vessel by fifty-four studs, which are threaded into the vessel flange and extend through the closure head flange. Conventional nuts and washers were originally supplied with the RV. Hydraulic nuts were procured to be used with the RV studs, as appropriate. Original nuts and washers continue to be used.

The Unit 1 RPV has a replacement RV closure head (RRVCH) which has a one-piece housing and is connected to the reactor vessel head adapter by a full penetration weld. The lower portion of the pressure vessel contains the latch assembly. Unit 2 has the original RV closure head and CRDMs with a latch housing and rod travel housing which are connected by a threaded, seal-welded maintenance joint. The stainless steel housing of the CRDM for Unit 2 is screwed and seal-welded onto the top of the nozzle penetration.

RCS high point vents are provided on the reactor vessel head. These vents are designed to vent noncondensible gases which may inhibit core cooling during natural circulation. Venting is directly to open areas of the containment to assure appropriate mixing with the containment air. The vents are sized to limit the required makeup flow rate to within the capability of the CVCS.

The RV flange and head are sealed by two hollow metallic O-rings. Seal leakage is detected by means of two leakoff communications: one between the inner and outer ring and one outside the outer O-ring.

The RV is Safety Class 1. Design and fabrication of the RV is carried out in strict accordance with ASME Section III, Class 1 requirements. The head flanges and nozzles are manufactured as forgings. The cylindrical portion of the vessel is made up of several shells, each consisting of formed plates joined by full penetration longitudinal weld seams. The hemispherical heads are made from dished plates. The RV parts are joined by welding, using the single or multiple wire submerged arc.

At all locations in the RPV where stainless steel and Inconel are joined, the final joining beads are Inconel weld metal in order to prevent cracking.

> Unit 1: The location of full penetration weld seams in the vessel bottom head are restricted to areas that permit accessibility during inservice inspection (ISI). There are no full penetration welds in the upper closure head.
>
> Unit 2: The location of full penetration weld seams in the upper closure head and vessel bottom head are restricted to areas that permit accessibility during ISI.

The shell is constructed of lower shell plates and intermediate shell plates, as well as the upper shell plates and flange. These plates are joined with a circumferential weld and longitudinal welds. The core (active fuel height) is across from the lower and intermediate shells.

In addition to the upper incore instrumentation, there are RV bottom port columns which carry the retractable, cold worked stainless steel flux thimbles that are pushed upward into the reactor core. Conduits extend from the bottom of the RPV down through the concrete shield area and up to a thimble seal line. The thimbles are closed at the leading ends and serve as the pressure barrier between the reactor pressurized water and the containment atmosphere.

Mechanical seals between the retractable thimbles and conduits are provided at the seal line. During normal operation, the retractable thimbles are stationary and move only during refueling or for maintenance, at which time a space of approximately 15-ft above the seal line is cleared for the retraction operation.

Boundary

The RPV evaluation boundary for LR is reflected on the LRBDs listed below. While the RPV is screened as in-scope within the RCS, it is evaluated as a subcomponent on its own.

The RPV evaluation boundary begins at the four (4) RPV inlet nozzle safe ends and terminates at the four (4) RPV outlet nozzle safe ends, with the RCS piping attached to the safe ends addressed in Section 2.3.1.3. The RPV boundary also includes fifty-three (53) penetrations for the CRDMs, two (2) penetrations for The RV Level Measuring System (RVLMS) and four (4) penetrations for the core exit thermocouple nozzle assemblies (CETNA). For Unit 1, the CRDMs are welded to the head. For Unit 2, this boundary consists of threaded canopy seals. Unit 2 also contains eighteen (18) plugged spare penetrations. The RPV boundary also includes the fifty-eight (58) RV lower head bottom mounted instrument nozzles used for the Incore Flux Mapping System and fifty (50) instrument nozzles used for core exit thermocouples.

The RPV evaluation boundary with the RVI, which are addressed in Section 2.3.1.2, is at the core support pads attached to the inside of the RPV.

The boundary includes the nozzles to the RPV head vent piping and the RV flange leakage monitoring piping and valves. The RPV head vent and RV flange leakage monitoring piping are covered in Section 2.3.1.3 for the RCS and attached piping.

Unit 1:

- M1-0250-LR

Unit 2:

- M2-0250-LR

Common:

- None.

System Intended Functions

The RV is a major component within the RCS and provides component level support to the RCS System intended functions which are defined in Section 2.3.1.3 for the RCS and attached piping.

Nuclear safety related functions of the RPV (10 CFR 54.4(a)(1)):

(1) Provide RCPB. The RPV provides a boundary for containing the reactor coolant under normal operating temperature and pressure conditions.

(2) Maintain reactor core geometry. The RPV contains the core, core supporting structures, control rods, and other parts directly associated with the core.

(3) Keep the reactor core subcritical for any mode of normal operation or event. The CRDMs of the RPV insert or withdraw rod cluster control assemblies within the core to control average core temperature and to shut down the reactor.

(4) Vent non-condensable gasses from the RCS. The Unit 2 RVCH and Unit 1 RRVCH each have a connection for venting the head to the Containment atmosphere through closed head vent valves.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The RCS is credited with providing reactor coolant inventory and pressure control and process monitoring including incore thermocouples during fire events.

(2) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for ATWS (10 CFR 50.62). The RCS is credited with RCPB integrity during an ATWS event.

(3) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The RCS and attached piping include components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(4) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63). The RCS is credited with maintaining RCPB integrity,

natural reactor coolant circulation for decay heat removal and process monitoring during a SBO event.

(5) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for Pressurized Thermal Shock (10 CFR 50.61). The RV beltline shell, including plates, forgings, and welds are subject to PTS analyses.

2.3.1.2. Reactor Vessel Internals

Description

The RVIs support the core, maintain fuel alignment, limit fuel assembly movement, maintain alignment between fuel assemblies and CRDMs, direct coolant flow past the fuel elements, direct coolant flow to the pressure vessel head, provide gamma and neutron shielding, and guides for the incore instrumentation. The RVI components are divided into three parts consisting of:

- the lower core support structure, including the entire core barrel and neutron shield pad assembly,
- the upper core support structure, and
- the incore instrumentation support structures.

Coolant flows from the vessel inlet nozzles down the annulus between the core barrel and the vessel wall and then into a plenum at the bottom of the vessel. It then reverses and flows up through the core support and through the lower core plate (LCP). The LCP is sized to provide the described inlet flow distribution to the core. After passing through the core, the coolant enters the region of the upper nozzles and flows directly through the vessel outlet nozzles. A small portion of the coolant flows between the baffle plates and the core barrel to provide additional cooling of the barrel.

The major containment and support member of the reactor internals is the lower core support structure. This support structure assembly consists of the core barrel, the core baffle, the LCP and support columns, the neutron shield pads, and the core support which is welded to the core barrel. The lower core support structure is supported at its upper flange from a ledge in the reactor vessel head flange and its lower end is restrained in its transverse movement by a radial support system attached to the vessel wall. Within the core barrel are an axial baffle and a LCP, both of which are attached to the core barrel wall and form the enclosure periphery of the assembled core. The LCP is a member through which the necessary flow distribution holes for each fuel assembly are machined. Fuel assembly locating pins (two for each assembly) are also inserted into this plate. Columns are placed between this plate and the core support of the core barrel. The neutron shield pad assembly consists of four pads that are bolted and pinned to the outside of the core barrel. A “key” is attached to the internals at equally spaced points around the circumference (of the core support). In the event of an abnormal downward vertical displacement of the internals following a hypothetical failure, energy absorbing devices limit the displacement after contacting the vessel bottom head. The energy absorbers, cylindrical in shape, are contoured on their bottom surface to the RV bottom head geometry.

The upper core support assembly consists of the top support plate assembly and the upper core support plate, between which are contained support columns and guide tube assemblies. The guide tube assemblies are fastened to the top support plate and are restrained by pins in the upper core plate. Additional guidance for the CRD shafts is provided by the upper guide tube which is attached to the upper support plate and control rod guide tube (CRGT). The upper core support assembly is positioned in its proper orientation with respect to the lower support structure by flat-sided pins pressed into the core barrel which in turn are engaged in slots in the upper core plate. Fuel assembly locating pins protrude from the bottom of the upper core plate. The upper core support assembly is restrained from any axial movements by a large circumferential spring which rests between the upper barrel flange and the upper core support assembly and is compressed by the reactor vessel head flange.

The incore instrumentation support structures consist of an upper system to convey and support thermocouples penetrating the vessel through the head and a lower system to convey and support flux thimbles penetrating the vessel through the bottom. The upper system utilizes the reactor vessel head penetrations. Instrumentation port columns are slip-connected to inline columns that are in turn fastened to the upper support plate. The thermocouples are carried through these port columns and the upper support plate at positions above their readout locations. In addition to the upper incore instrumentation, there are RV bottom port columns which carry the retractable, cold worked stainless steel flux thimbles that are pushed upward into the reactor core. The thimbles are closed at the leading ends and serve as the pressure barrier between the reactor pressurized water and the containment atmosphere. Bottom-Mounted Instrumentation (BMI) wear reduction sleeves are installed in the RV lower internals instrumentation columns of Unit 1.

Boundary

The RVI boundary includes the upper core support structure, lower core support structure, and incore instrumentation support structure. Also included in the RVI boundary are the fuel assemblies and the rod cluster control assemblies, including the spider assembly and rodlets. The boundary between the rod cluster control assembly and the CRDM is at the rod cluster control assembly spider assembly coupler.

While the control rods, core exit and RV Level Indicating System (RVLIS) thermocouples, and fuel assemblies are included within the scope of LR, they are screened as active or short-lived components and are not subject to AMR. Additionally, the irradiation specimen basket, which is contained in the lower core support structure and attached to the neutron panels, does not serve any LR intended function and is, therefore, not in the scope of LR or subject to AMR.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

1) Maintains core assembly geometry within the reactor to ensure core cooling, core reactivity control, and the integrity of the fuel cladding as a radioactive material barrier.

2) Provides structural support and alignment for the core, reactivity control components, and instrumentation.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

None.

(1) The Unit 1 BMI wear reduction sleeves are grouped with their corresponding BMI column bodies in Table 3.1.2-2, as these sleeves are completely contained within the instrumentation column bodies.

2.3.1.3. Reactor Coolant System and Attached Piping

Description

The RCS consists of four parallel, similar, heat transfer loops, each consisting of a reactor coolant pump (RCP) and SG, connected to the RPV. In addition, the system includes a pressurizer (PZR), pressurizer relief tank (PRT), connecting piping, and the instrumentation necessary for operational control and protection. During operation, the RCS transfers the heat generated in the core to the SGs where steam is produced to drive the turbine generator. Borated demineralized water is circulated in the RCS at a flow rate and temperature consistent with achieving the reactor core thermal-hydraulic performance. The water also acts as a neutron moderator and reflector, and as a solvent for the neutron absorber used in chemical shim control. The RCPB provides a barrier against the release of radioactivity generated within the reactor and is designed to ensure a high degree of integrity throughout the life of the plant. RCS pressure is controlled by the use of the PZR where water and steam are maintained in equilibrium by electrical heaters and water sprays. Spring loaded safety valves and power operated relief valves (PORVs) are mounted on the PZR and discharge to the PRT, where the steam is condensed and cooled by mixing with water. RCS high point vents are provided on the reactor vessel head and on the pressurizer. These vents are designed to vent non-condensable gases which may inhibit core cooling during natural circulation. Venting is directly to open areas of the containment to assure good mixing with the containment air. The vents are sized to limit the required makeup flow rate to within the capability of the CVCS.

The RCPs ensure an adequate core cooling flow rate and hence sufficient heat transfer, to maintain a departure from nucleate boiling ratio (DNBR) greater than the limit value within the parameters of operation. The required net positive suction head (NPSH) is by conservative pump design always less than that available by system design and operation. Sufficient pump rotation inertia is provided by a fly wheel, in conjunction with the impeller and motor assembly, to provide adequate flow during coastdown. This flow following an assumed loss of pump power aids in the development of a thermal gradient for initiation of natural circulation while providing the core with adequate cooling.

The RCPs are vertical, single stage, centrifugal, shaft seal pumps designed to pump large volumes of main coolant at high temperatures and pressures. Each pump consists of three areas from bottom to top. They are the hydraulics, the shaft seals, and the motor.

1. The hydraulic section consists of an impeller, diffuser, casing, thermal barrier, heat exchanger, radial bearing, main flange, motor stand, and pump shaft.

2. The motor section consists of a vertical solid shaft, squirrel cage induction type motor, and oil lubricated double thrust bearing, two oil lubricated radial bearings, and a flywheel.

3. The shaft seals section consists of three seals contained within the main flange and seal housings.

Above the impeller is a thermal barrier heat exchanger which limits heat transfer between hot system water and seal injection water. Component cooling water (CCW) is supplied to the thermal barrier heat exchanger. High-pressure seal injection water is introduced through the thermal barrier wall. A portion of this water flows through the radial bearing and the seals; the remainder flows down the shaft through the thermal barrier where it acts as a buffer to prevent system water from entering the radial bearing and seal section of the unit. The thermal barrier heat exchanger provides a means of cooling system water to an acceptable level in the event that seal injection flow is lost. The water lubricated journal type pump bearing, mounted above the thermal barrier heat exchanger, has a self-aligning spherical seat.

In the event of a loss of seal injection and CCW flow to the thermal barrier heat exchanger, RCS fluid begins to travel along the RCP shaft and displaces the cooler seal injection water. Once the temperature within the number 1 seal reaches the actuation temperature range of the SHIELD Shutdown Seal (SSDS), the SSDS will activate to limit leakage from the RCS through the RCP seals.

The loss of reactor coolant through the RCP seal package is limited when the SSDS polymer ring activates around the number 1 seal sleeve.

The RCP motor bearings are of conventional design. The radial bearings are the segmented pad type, and the thrust bearings are tilting pad bearings. All are oil lubricated. The lower radial bearing and the thrust bearings are submerged in oil, and the upper radial bearing is oil fed from a viscosity pump integral with the thrust runner. CCW is supplied to the two oil coolers on the pump motor.

The RCS piping is designed and fabricated to accommodate the system pressures and temperatures attained under all expected modes of plant operation or anticipated system interactions. The piping in the RCS is Safety Class 1 and is designed and fabricated in accordance with the ASME Section III, Class 1 requirements. Stainless steel pipe conforms to ANSI B36.19 for sizes 1/2-in through 12-in and wall thickness Schedules 40S through 80S. Stainless steel pipe outside of the scope of ANSI B36.19 conforms to ANSI B36.10. The CPNPP Unit 1 and 2 pressurizer surge line design utilizes schedule 160 piping with the exception of a one-ft section of schedule 140 piping in the Unit 1 pressurizer surge line. All butt welds, branch connection nozzle welds, and boss welds are of a full penetration design. Socket weld fittings and socket joints conform to ANSI B16.11.

The pressurizer surge line connects the pressurizer to one RCS hot leg. The line enables continuous coolant volume pressure adjustments between the RCS and the pressurizer. The pressurizer is a vertical, cylindrical vessel with hemispherical top and bottom heads. The surge line nozzle and removable electric heaters are installed in the bottom head. A thermal sleeve is provided to minimize stresses in the surge line nozzle. A screen at the surge line nozzle and baffles in the lower section of the pressurizer prevent an insurge of cold water from flowing directly to the steam/water interface and assist mixing. Spray line nozzle, relief and safety valve connections are located in the top head of the vessel. Spray flow is modulated by automatically controlled air operated valves. The spray valves also can be operated manually by a switch in the Control Room. A small, continuous spray flow is provided through a manual bypass valve around the power operated spray valves to assure that the pressurizer liquid is homogeneous with the coolant and to prevent excessive cooling of the spray piping.

The Pressurizer Relief Discharge System does not constitute part of the RCPB per 10 CFR 50.2 since all of its components are downstream of the RCS safety and relief valves (FSAR Section 5.4.11.3). The steam and water discharged from the various safety and relief valves inside the containment is routed to the PRT (PRT) if the discharged fluid is of reactor grade quality. The tank normally contains water and a predominantly nitrogen atmosphere. In order to obtain effective condensing and cooling of the discharged steam, the tank is installed horizontally, and the steam is discharged through a sparger pipe located near the bottom, under the water level. Cold water is drawn from the Reactor Makeup Water System, or the content of the tank is circulated through the reactor coolant drain tank heat exchanger of the Waste Processing System and back into the spray header. The nitrogen gas blanket is used to control the atmosphere in the tank and to allow room for the expansion of the original water plus the condensed steam discharge.

Boundary

RCS components and attached piping, in other systems, that comprise the RCPB are ASME Code / ANSI Safety Class 1. These RCPB components start with the piping just outside of the RPV nozzle safe ends and continue through all four reactor coolant loops (RCLs) back to the RPV nozzle safe ends. Each loop includes interfaces with other systems. The RCS and attached piping in other systems include the CVCS, RHRS, and Safety Injection System (SIS).

In-scope components in the RCS and attached piping are those that maintain the pressure boundary of the system starting with the piping just outside of the RV. The RCS and attached piping begin with the Class 1 piping from the RV and continues through all four loops' piping and components back to the RV. Each loop contains boundaries that interface with other Class 1 systems. The interfaces within each loop include SI, RHR, Process Sampling, and Waste Processing. Class 1 piping and components in these other systems are addressed under the AMR for the RCS and attached piping, with the exception of the RV and steam generators, which are addressed separately.

Each RCS loop interfaces with the SIS leading up to the accumulator tanks. RCS loop drains interface with the Waste Processing System. The RCS and attached piping interfaces with the Oil Spillage Protection System (OSPS) which includes the OSPS tanks (one per loop) and their attached piping, pans, hoses, and reducers, etc. These are discussed in the FPS Section 2.3.3.7.

The boundaries also include the piping, valves, and components connected to the PRT and RCS standpipe. These NNS components are attached to nuclear safety related components and/or contain liquid. These NNS components have the potential to impact nuclear safety related functions due to aging.

The evaluation boundary for the RCS and attached piping is shown on the following LRBDs:

Unit 1:

- M1-0250-LR
- M1-0251-LR
- M1-0253-LR
- M1-0253-A-LR
- M1-0260-LR

- M2-0263-LR
- M2-0263-B-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide RCPB. The RCS provides a boundary for containing the reactor coolant under normal operating temperature and pressure conditions. The PORVs and safety valves prevent an overpressure condition during plant transients.

(2) Sense process conditions and generate signals for reactor trip or ESF actuation. The RCS instrumentation provides system pressure, temperature, pressurizer water level, and reactor coolant flow inputs to reactor trip and ESF actuation systems.

(3) Provide and maintain sufficient reactor coolant inventory for core cooling. Coolant is circulated at the flow and temperature required for achieving the reactor core thermal-hydraulic performance. The RCS circulates reactor coolant either by forced circulation with the RCPs or by natural circulation to transfer sufficient heat from the reactor core to the SG secondary fluid during normal operation and anticipated operational occurrences so that reactor core thermal limits are not exceeded.

(4) Remove residual heat from the reactor core through natural or forced circulation following DBAs. The RCS provides connections with the Residual Heat Removal System (RHRS) and provides a portion of the flow path to support decay heat removal.

(5) Maintain the dose consequences within the guidelines of 10 CFR 50.67 or 10 CFR Part 100. The RCS provides sufficient core cooling to ensure that the nuclear fuel and the reactor coolant design limits are not exceeded.

(6) Vent non-condensable gasses from the RCS. The RCS has connections to the CVCS and Boron Recycle System (BRS) which allows for the ventilation of these non-condensable gases.

(7) Provide a path for coolant to the core following a LOCA.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The RCS is credited with providing reactor coolant inventory and pressure control and process monitoring including incore thermocouples during fire events.

(2) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for ATWS (10 CFR 50.62). The RCS is credited with RCPB integrity during an ATWS event.

(3) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The RCS and attached piping include components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(4) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63). The RCS is credited with maintaining RCPB integrity, natural reactor coolant circulation for decay heat removal and process monitoring during a SBO event.

2.3.1.4. Steam Generators

Description

The SGs are a major component within the RCS. The system description for the RCS is not repeated here, and instead focuses on the SGs. Although the SGs are not a system at CPNPP, they are a major component with a significant number of subcomponents that warrant a separate AMR. A technical description of the SGs is provided below to facilitate the AMR.

The Unit 1 SGs were replaced during refueling outage 1RF12 in Spring 2007. The Unit 2 SGs are original to CPNPP. The Unit 1 SGs are model Delta 76 vertical SGs, and the Unit 2 SGs are model D-5 vertical SGs. Each unit has four SGs, one for each RCL.

The SGs are Westinghouse vertical U-tube units containing Inconel tubes and equipped with integral moisture separation equipment to reduce the moisture content of the steam to 0.10 percent for Unit 1 and to 0.25 percent or less for Unit 2.

Unit 1 Model Delta 76 SG Description

On the primary side, the reactor coolant flows through the inverted U-tubes, entering and leaving through nozzles located in the hemispherical bottom head of the SG. The head is divided into inlet and outlet chambers by a vertical divider plate extending from the head to the tubesheet. Steam is generated on the shell side, flows upward, and exits through the outlet nozzle at the top of the vessel. During normal operation, subcooled feedwater is supplied from the plant Feedwater System and enters the SG through the main (or sometimes auxiliary) feedwater inlet nozzle located in the upper shell of the SG. Inside the SG, the feedwater is joined by the recirculating water separated from the steam-water mixture by the moisture separators, producing a subcooled mixture in the upper plenum that is slightly below saturation temperature. The subcooled mixture flows down the downcomer annulus formed by the inner diameter of the SG shell and the O.D. of the wrapper, then enters the lower tube bundle through an opening between the lower edge of the wrapper and the secondary surface of the tubeplate. Subsequently the water-steam mixture flows upward through the tube bundle and into the steam drum section, where individual centrifugal moisture separators remove most of the entrained water from the steam. The steam continues to the secondary separators for further moisture removal, increasing its quality to a minimum of 99.9 percent. The moisture separators recirculate the separated water through the annulus between the shell and tube bundle wrapper. The returning flow then combines with the feedwater for another passage through the SG. Dry steam exits through the outlet nozzle which is provided with a steam flow restrictor.

Unit 2 Model D-5 SG Description

On the primary side, the reactor coolant flows through the inverted U-tubes, entering and leaving through nozzles located in the hemispherical bottom head of the SG. The head is divided into inlet and outlet chambers by a vertical divider plate extending from the head to the tubesheet. Steam is generated on the shell side, flows upward, and exits through the outlet nozzle at the top of the vessel. During normal operation, feedwater flows through a flow restrictor, directly into the counter flow preheat section and is heated almost to saturation temperature before entering the boiler section. Subsequently the water-steam mixture flows upward through the tube bundle and into the steam drum section, where individual centrifugal moisture separators remove most of the entrained water from the steam. The steam continues to the secondary separators for further moisture removal, increasing its quality to a minimum of 99.75 percent. The moisture separators recirculate the separated water through the annulus between the shell and tube bundle wrapper via the space formed by the distribution plate, between the tubesheet and the preheat section. The returning flow then combines with the already preheated water-steam mixture for another passage through the SG. Dry steam exits through the outlet nozzle which is provided with a steam flow restrictor.

Boundary

The SGs interface with the MS, FW, and AFW Systems. The SGs appear on the LRBDs for each of the interfacing systems and are highlighted on the RCS LRBDs M1-0250-LR and M2-0250-LR. The SG boundary includes the connections at nozzles and safe ends from the interfacing system piping to the channel head, shell, and internals, including secondary side support structures.

Unit 1:

- M1-0250-LR

Unit 2:

- M2-0250-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

Reactor Coolant System

(1) Remove residual heat from the reactor core through natural or forced circulation following DBAs.

(2) Provide a boundary for containing the coolant under operating temperature and pressure conditions and for limiting leakage (and activity release) to the containment atmosphere.

Feedwater System

(3) Provide feedwater to maintain the water inventories in the SGs.

Auxiliary Feedwater System

(4) Maintain water levels in the SGs in the event of a LOCA.

Main Steam System

(5) Support containment pressure boundary.

(6) Deliver the required quantity and quality of steam to the auxiliary feedwater pump turbine.

(7) Provide controlled heat release from the reactor during normal and emergency conditions.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain integrity of NNS components such that no physical interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

Reactor Coolant System

(1) Utilized to achieve reactor coolant inventory control and reactor coolant pressure control during a Fire Safe Shutdown regulated event (10 CFR 50.48).

(2) Maintain its pressure boundary and provide core cooling during a SBO regulated event (10 CFR 50.63).

(3) Provides SG water level input to the AMSAC (10 CFR 50.62).

(4) Contains EQ components that are nuclear safety related and located in harsh environments (10 CFR 50.49).

Feedwater System

(5) Provide system isolation and a flow path for AFW during a SBO regulated event (10 CFR 50.63).

Auxiliary Feedwater System

(6) Provide auxiliary feedwater flow from the CST to the SGs to ensure decay heat removal during a SBO (10 CFR 50.63) and Fire Safe Shutdown (10 CFR 50.48) regulated events.

Main Steam System

(7) Provide steam to the auxiliary feedwater pump turbines during a SBO regulated event (10 CFR 50.63).

(8) Maintain decay heat removal during SBO (10 CFR 50.63) and Fire Safe Shutdown (10 CFR 50.48) regulated events.

2.3.2. Engineered Safety Features

The following systems are addressed in this section:

- Combustible Gas Control System (2.3.2.1)
- Containment Isolation System (2.3.2.2)
- Containment Spray System (2.3.2.3)
- Residual Heat Removal System (2.3.2.4)
- Safety Injection System (2.3.2.5)

Note – Habitability and filtration engineered safety features are addressed in Section 2.3.3 with other auxiliary plant ventilation systems. In addition, the portions of RHRS and SIS that are in the RCPB (ASME Class 1) are addressed in Section 2.3.1.3

2.3.2.1. Combustible Gas Control System

Description

The purpose of the Combustible Gas Control System (CGCS) is to limit the concentration of hydrogen in containment following a DBA. Buildup of hydrogen gas inside containment may be generated by reactions such as zirconium metal with water, corrosion of materials of construction and exposure of the organic cable materials to radiation and radiolysis of aqueous solution in the core sump. This buildup could result in hydrogen burns or hydrogen detonations that could jeopardize containment integrity. The CGCS limits this buildup by utilizing the hydrogen purge subsystem that purges containment through filters to reduce radioactive releases.

The CGCS consists of the Hydrogen Purge System along with the Hydrogen Monitoring System. Previously the CGCS also contained the hydrogen recombiner subsystem, however that subsystem has been abandoned in place. The Hydrogen Purge System functions to provide controlled purging of the containment atmosphere to aid in cleanup post LOCA. When the system operates, it can maintain the hydrogen concentration in containment below the lower flammability limit post LOCA. The Hydrogen Monitoring System monitors the hydrogen partial pressure in several well-ventilated areas of the RCB in order to obtain the typical values for hydrogen gas concentration.

The Hydrogen Purge System within the CGCS consists of two 700 cubic-ft per minute (cfm) blowers for supply, inlet and outlet ductwork, piping, isolation valves, a flow control valve, two atmospheric cleanup systems and two exhaust fans. The blowers are capable of transporting 700 cfm of fresh, filtered air to the containment. Air is drawn from either containment as required, passed through a filter plenum (particulate, iodine absorbers, high efficiency particulate air (HEPA) filters) and discharged through the plant discharge duct. A demister and heater are used to maintain the humidity entering the filters below 70 percent. Two trains are provided (one train is required to operate), each capable of controlling the design airflow of 700 cfm when the containment is less than 5.8 psig.

The Hydrogen Monitoring System continuously monitors the hydrogen content of containment atmosphere at four different elevations in containment during normal plant operations and will be operational within 90 minutes following a LOCA. The Hydrogen Purge System is manually operated and is isolated from containment by normally closed valves.

Boundary

Nuclear safety related components in the CGCS are those that maintain the pressure boundary of containment starting downstream from the class 2 boundary at hydrogen purge supply isolation valves, and through pipe penetrations MIII-0018 and MIII-0019 as well as 2-MIII-0018 and 2-MIII-0019.

NNS affecting nuclear safety related components in the Hydrogen Purge System are the class 5 piping connecting to the class 2 boundary upstream of the hydrogen purge supply isolation dampers to the ductwork connections.

The LR boundaries are reflected on the LRBDs listed below.

Unit 1:

- M1-0301-LR

Unit 2:

- M2-0301-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide isolation of lines penetrating containment to maintain the containment pressure boundary.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain integrity of NNS components such that no interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Perform a function that demonstrates compliance with the Commission's regulations for the EQ program (10 CFR 50.49). The CGCS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

2.3.2.2. Containment Isolation System

Description

The Containment Isolation System (CIS) allows the normal or emergency passage of fluids through the containment boundary while preserving the ability of the boundary to limit the escape of fission products from postulated accidents. The CIS, in conjunction with other interfacing systems, is designed to monitor the development of gross leakages in containment and to limit radioactive emission from the containment during normal operations and in response to abnormal/accident conditions.

The CIS is a virtual system that comprises components from multiple plant systems. Rather than separate components from those plant systems that are in the scope of LR, for inclusion in the CIS, this section is focused on the Containment penetrations that are not part of another system. Unique CIS components include Containment personnel airlock and emergency airlock operating systems; Containment leak rate testing; and Containment pressurization/pressure sensing instrumentation components.

Containment personnel airlock (airlock operating system only)

Access to the Containment structure is provided by a personnel airlock. The personnel airlock is an electro-hydraulically operated double-door assembly. Each door is hinged and gasketed, with leakage test taps aligned to the annulus between the gasket sealing surfaces. Both doors are interlocked so that if one door is open, the other cannot be activated. Both doors are also furnished with hydraulic actuators as well as manual pressure equalizing valves which can be operated by persons leaving or entering the personnel hatch. Test connections for the airlocks are isolated by blind flanges or caps.

The Hydraulic System which constitutes the personnel airlock operating mechanism contains some non-metallic seals and components necessary for it to perform its design function. These components are part of active components or are shaft seals which are grouped with valve packing and are considered consumables. In normal use during the opening and closing of the airlock door, the hydraulic components are normally pressurized to between 100 psig to 500 psig. Any leakage or failure would be readily visible at the point of Containment ingress and egress.

Containment Airlock Equalization and Hydraulic Systems contain components such as rotary actuator cylinders, locking ring cylinders, valves, and tubing. There are differences in design of the Containment personnel Airlock Hydraulic Systems between Units 1 and 2. The number of attachments and the type and number of components which are nuclear safety related or NNS are different.

Containment emergency personnel airlock (airlock operating system only)

An emergency airlock is provided for access to Containment in the event of a LOCA. The emergency airlock is a manually operated double-door assembly. Both doors of the emergency airlock are furnished with manually operated pressure-equalizing connection and valves which are interlocked with door operations.

Containment leak rate testing

Containment integrated leak rate testing is performed to verify the leakage rate is within acceptable limits, thus ensuring the ability of Containment to limit the escape of fission products. Containment leakage rate test, pressurization/pressure sensing penetrations consist of pipes or sleeves embedded in the Containment wall concrete, welded to the Containment liner and with installed blind flanges at each end. A test connection is provided so that the space between the end flanges can be pressurized in order to measure the leakage rate. The leak rate test and maintenance connections are each equipped with a bolted blind flange with locked closed valves outside the Containment, or a bolted blind flange both inside and outside the Containment. Containment penetrations MIV-0005, -0006, and -0007 have threaded plugs.

Containment pressurization/pressuring-sensing instrumentation

There are instrument lines which penetrate the Containment that are required to remain functional following a LOCA or steam line break. These lines sense the pressure of the Containment atmosphere and transmit this pressure to instruments outside the Containment. Each Containment pressure sensing instrument constitutes a closed, liquid-filled system sealed on the inside of the Containment by a diaphragm and on the outside by the pressure. Signals derived from these instruments initiate the SI, Containment isolation and Containment spray. Isolation is provided by means of sealed bellows connected to a fluid-filled tube. The arrangement consists of a double isolation barrier. If the instrument line breaks outside the Containment, leakage of the Containment atmosphere is prevented by virtue of the sealed bellows. If the instrument line breaks inside the Containment, leakage is prevented by a leak-tight diaphragm installed in the pressure instrument which is designed to withstand the full containment design pressure.

Boundary

The Containment penetrations are listed in FSAR Tables 6.2.4-1, 6.2.4-2, 6.2.4-3, 6.2.4-4, and 6.2.4-6. The majority of the piping penetrations are linked to a system in the scope of LR. In these instances, containment isolation is identified as a system intended function in Sections 2.3.2, 2.3.3 and 2.3.4. Furthermore, the electrical penetrations, airlock, emergency airlock, equipment hatch, and fuel transfer tube, along with piping/tubing penetration assemblies are within the Containment structural evaluation boundary described in Section 2.4.1.

As such, the CIS evaluation boundary is limited to the components associated with Containment (overall) leak rate testing, Containment pressurization/pressure sensing instrumentation, and the operating/equalization components up to the attachment to the personnel and emergency airlocks. The CIS LR boundaries are reflected on the LRBDs listed below.

Unit 1:

- M1-0245-LR
- M1-0301-A-LR

Unit 2:

- M2-0245-LR
- M2-0245-A-LR
- M2-0301-A-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The CIS allows normal and emergency passage of fluids and personnel through the containment boundary.

(2) The CIS minimizes leakage of radioactive materials through fluid lines penetrating containment in the event of a postulated accident.

(3) The CIS ensures that the offsite radiological consequences of a main steam (MS) line rupture or LOCA are within the guidelines of 10 CFR Part 100.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

None.

Piping	Pressure boundary Leakage boundary (spatial) Structural integrity (attached)
Tank (airlock hydraulic)	Leakage boundary (spatial)
Tubing	Pressure boundary Leakage boundary (spatial) Structural integrity (attached)
Valve body	Pressure boundary Leakage boundary (spatial) Structural integrity (attached)

In addition to those components specifically excluded in 10 CFR 54.21(a)(1)(i), such as instruments, the following CIS components are within the scope of LR, but not subject to AMR:

- Pump seals, bearings, motors, rotary actuators, and locking rings - perform their function with moving parts.
- Containment personnel airlock hydraulic pumps are periodically replaced and are therefore short lived and not subject to AMR.

2.3.2.3. Containment Spray System

Description

The Containment Spray System (CSS) is an ESF System provided to mitigate the consequences of a LOCA, a MS line break inside the Containment, or a feedwater line break inside the Containment. CSS components are located in the Safeguards Building, the Containment Building and the yard.

The CSS has dual functions of removing both heat and fission-product iodine from the post-accident Containment atmosphere. The purpose of the CSS is to function with ECCS to ensure that Containment pressure and temperature do not exceed the design parameters for all accidents including a LOCA. The purpose of the CSS is also to ensure that offsite radiological consequences are within the limits of 10 CFR Part 100 by reducing the fission product concentration within the Containment atmosphere. The spray headers and nozzles arrangement for the CSS is designed to provide a maximum spray coverage in the Containment.

Upon system activation during a LOCA, adequate Containment cooling is provided in sequential modes:

1. The CSS initially supplies the containment spray headers with borated water from the RWST. A chemical additive subsystem is included to inject a buffering solution Sodium Hydroxide (NaOH) into the borated spray water to enhance iodine removal from the Containment atmosphere and retention in the spray water.

2. When the water level in the RWST reaches the low-level set point, the water source is swapped to the Containment Recirculation Sump. Water from the sump is still sprayed through the spray headers, after it is cooled by the Containment spray heat exchangers, to provide for the continued cooling of the Containment atmosphere.

The CSS includes two redundant trains, each with two pumps, a heat exchanger, and spray nozzles.

Boundary

The CSS boundaries for LR are reflected on the LRBDs listed below.

In-scope components in the CSS are those that maintain the pressure boundary of the system starting from the RWST to the nozzles of the ring headers in containment. The components that are subject to AMR includes two containment spray pumps (total four pumps for two trains), heat exchanger cooled by the CCWS (one per train), ring header with nozzles, isolation valves, associated piping, instrumentation, and controls. The RWST, containment recirculation sumps, and piping from the containment spray pumps, are also part of the CSS.

The CSS also includes a chemical additive subsystem which includes the following in-scope components: a chemical additive tank (CAT), piping, chemical eductors, and piping associated with the Nitrogen System. The CSS also includes NNS components such as the vents and drains, valve isolation tanks, guard pipes, and the expansion joints.

The components associated with providing cooling to the bearings of the containment spray pumps are treated as part of the CSS. The containment spray pump seal Coolers are also part of the CSS but are shown on the LRBDs for the CCWS.

Unit 1:

- M1-0232-LR
- M1-0232-A-LR

Unit 2:

- M2-0232-LR
- M2-0232-A-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Support containment pressure boundary.

(2) Provide for long-term post-accident cooling to the RCB.

(3) Provide and maintain sufficient inventory for containment atmosphere cooling.

(4) Ensure that containment pressure and temperature do not exceed the design parameters for all accidents including LOCAs.

(5) Ensure that offsite radiological consequences are within the limits of 10 CFR Part 100 by reducing the fission product concentration within containment.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provide a source of borated water (RWST) during a Fire Safe Shutdown regulated event (10 CFR 50.48).

(2) Perform a function that demonstrates compliance with the Commission's regulations for the EQ program (10 CFR 50.49). The CSS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

2.3.2.4. Residual Heat Removal System

Description

The RHRS transfers heat from the RCS to the CCWS to reduce the temperature of the reactor coolant to the cold shutdown temperature at a controlled rate during the second part of normal plant cooldown and maintains this temperature until the plant is started up again.

Parts of the RHRS also serve as flowpaths for the ECCS during the injection and recirculation phases of a LOCA. The RHRS also is used to transfer refueling water between the refueling cavity and the RWST at the beginning and end of the refueling operations.

The RHRS, in conjunction with the Steam and Power Conversion (S&PC) Systems, is designed to transfer the fission production decay heat and other residual heat from the reactor core within acceptable limits. The crossover from the S&PC Systems to the RHRS occurs at approximately 350 degrees Fahrenheit (°F) and 425 pounds per square-inch gauge (psig).

Suitable redundancy at temperatures below approximately 350°F is accomplished with the two RHR pumps (located in separate compartments with means available for draining and monitoring of leakage), the two heat exchangers, and the associated piping, cabling, and electric power sources. The RHRS is capable of operating on either onsite or offsite electrical power systems. Suitable redundancy at temperatures above approximately 350°F is provided by the four SGs and associated piping systems.

In the event of a fire, the RHRS is required to cool the RCS from hot shutdown to cold shutdown. In the event of a DBA on one unit, the other unit is required to be capable of an orderly shutdown and cooldown.

The RHRS is designed to be isolated from the RCS whenever the RCS pressure exceeds the RHRS design pressure. The RHRS is isolated from the RCS on the suction side by two motor operated valves in series on each suction line. Each motor operated valve is interlocked to prevent its opening if RCS pressure is greater than 425 psig. The RHRS is isolated from the RCS on the discharge side by two check valves in each return line. Also provided on the discharge side is a normally open motor operated valve downstream of each RHRS heat exchanger.

Each inlet line to the RHRS is equipped with a pressure relief valve designed to relieve the combined flow of all the charging pumps at the relief valve set pressure. These relief valves also protect the system from inadvertent over-pressurization during plant cooldown or startup. Each discharge line from the RHRS to the RCS is equipped with a pressure relief valve designed to relieve the maximum possible back-leakage through the valves isolating the RHRS from the RCS.

The RHRS consists of two residual heat exchangers, two RHR pumps, and the associated piping, valves, and instrumentation necessary for operational control. The inlet lines to the RHRS are connected to the hot legs of two RCLs, while the return lines are connected to the cold legs of each of the RCLs. These return lines are also the ECCS low head injection lines.

During RHRS operation, reactor coolant flows from the RCS to the RHR pumps, through the tube side of the residual heat exchangers, and back to the RCS. The heat is transferred to the CCW circulating through the shell side of the residual heat exchangers.

The RCS cooldown rate is manually controlled by regulating the reactor coolant flow through the tube side of the residual heat exchangers. A line containing a flow control valve bypasses each residual heat exchanger and is used to maintain a constant return flow to the RCS. Instrumentation is provided to monitor system pressure, temperature, and total flow.

The RHRS is also used for filling the refueling cavity before refueling. After refueling operations, water is pumped back to the RWST until the water level is brought down to the flange of the RV. The remainder of the water is removed via a drain connection at the bottom of the refueling canal.

When the RHRS is in operation, the water chemistry is the same as that of the reactor coolant. Provision is made for the Process Sampling System to extract samples from the flow of reactor coolant downstream of the residual heat exchangers. A local sampling point is also provided on each RHR train between the pump and heat exchangers.

In its capacity as the low head portion of the ECCS, the RHRS provides long-term recirculation capability for core cooling following the injection phase of the LOCA. This function is accomplished by aligning the RHRS to take fluid from the containment sump, cool it by circulation through the residual heat exchangers, and supply it to the core directly as well as via the centrifugal charging pumps (CCPs) and SI pumps.

Boundary

The boundaries of the RHRS are given below.

Normal standby alignment:

- From the outlet of the RWST check valves to the RHRS pump suction,
- Through the RHRS pumps and heat exchangers (including bypass flow lines),
- To the downstream side of the heat exchanger outlet valves.

Emergency water source alignment (cold leg recirculation):

- Begins at the valve isolation tank, downstream of the containment recirculation sump,
- Continues to the suction of each RHRS pump, and
- To the downstream side of the heat exchanger outlet valves.

Normal unit shutdown alignment and refueling alignment:

- Begins at the downstream side of the motor-operated valves on the letdown lines from the RCS loop hot legs,
- Through a containment penetration and continues to the suction piping of each of the RHRS pumps, and
- To the downstream side of the heat exchanger outlet valves.
- The RHRS reactor coolant isolation valves provide the interface with the RCS. The boundary includes the lines to the pump suction relief valves, and ends at the discharge of the relief valves, which vents to the RCS PRT.

Included in all alignments are the cross-connect line on the outlet of the RHRS heat exchangers and ends on the upstream side of the discharge valve to the piping, which constitutes one of the interfaces with CVCS. Included in this boundary are minimum flow recirculation lines on each RHR loop, which connects the piping downstream of each RHR heat exchanger with its associated RHRS pump suction line.

All associated piping, components, and instrumentation contained within the flow path described above are included in the system evaluation boundary.

The RHRS heat exchangers and pump seal coolers are included in the scoping boundary. The cooling side of these heat exchangers are provided by CCWS. The drain and vent lines from the tube side of the residual heat exchangers are included in the boundary up to the downstream side of the manual isolation valves to the Vents And Drains System (VD).

The RHRS boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0260-LR
- M1-0263-B-LR

Unit 2:

- M2-0260-LR
- M2-0263-A-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Maintain integrity of the RCPB

(2) Support containment pressure boundary

(3) Provide low pressure injection to the RCS as part of the ECCS to provide core cooling and additional shutdown margin including injection from the RWST and recirculation of the RCS from the containment sump

(4) Provide suction from the containment sump to the SI and CCPs during cold leg and hot leg recirculation

(5) Provide for cooling of the RCS during normal plant cooldown and shutdown operations

(6) Provide and maintain sufficient reactor coolant inventory for core cooling

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The RHRS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(2) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The RHRS provides decay heat removal during a Fire Safe Shutdown regulated event.

2.3.2.5. Safety Injection System

Description

The SIS is a part of the ECCS, which is designed to cool the reactor core and provide shutdown capability following initiation of the following accident conditions:

1. Pipe breaks in the RCS which cause a discharge larger than that which can be made up by the normal makeup system, up to and including the instantaneous circumferential rupture of the largest pipe in the RCS

2. Rod cluster control assembly ejection accident

3. Pipe breaks in the steam system, up to and including the instantaneous circumferential rupture of the largest pipe in the steam system

4. A SG tube failure

The primary function of the ECCS is to remove the stored and fission product decay heat from the reactor core during accident conditions.

The SIS contains the SI pumps and accumulator tanks along with the associated piping, valves, instrumentation, and other related equipment. These components are part of the ECCS which is designed such that a minimum of three accumulators, one charging pump, one SI pump, and one RHR pump together with their associated valves and piping will assure adequate core cooling in the event of a design basis LOCA. The SIS is designed with two redundant trains of active components.

The accumulators are pressure vessels partially filled with borated water and pressurized with nitrogen gas. During normal operation, each accumulator is isolated from the RCS by two check valves in series. Should the RCS pressure fall below the accumulator pressure, the check valves open and borated water is forced into the RCS. One accumulator is attached to each of the cold legs of the RCS.

The SI pumps, upon receipt of a SI signal, deliver water to the RCS from the RWST during the injection phase and from the containment sump via the RHR pumps during the recirculation phase. The pumps inject water into the RCS cold legs or hot legs.

Boundary

The SIS boundaries for LR are reflected on the LRBDs listed below.

Class 1 nuclear safety related components in the SIS and associated downstream check valves function as the interfacing boundary of the RCS leading to the RV. The boundaries of the SIS are given below.

- From the discharge header of the charging pumps to the RCS loop cold legs

- SI pump discharge piping up to the isolation valves outside the containment

- From the accumulators to the RCS loop cold legs

- SI pump discharge piping from the isolation valves outside the containment to the RCS hot legs and SIS cold legs

- SI pump suction

Other components within the system evaluation boundary include those components associated with the RWST, the SI pumps, the accumulator tanks, downstream of the charging pumps, and downstream/upstream of the RHR heat exchangers. All eventually feed into Class 1 components (or divert to the NNS test paths). The carbon steel piping associated with the N_2 accumulators that feed nitrogen into the accumulator tanks housing borated water are also in scope.

Unit 1:

- M1-0261-LR
- M1-0262-LR
- M1-0263-LR
- M1-0263-A-LR
- M1-0263-B-LR

Unit 2:

- M2-0261-LR
- M2-0262-LR
- M2-0263-LR
- M2-0263-A-LR
- M2-0263-B-LR
- M2-0263-C-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Injects borated water into the RCS cold legs to remove stored and fission product decay heat from the reactor core during accident conditions.

(2) Supports recirculation of core coolant back to the RV following a DBA.

(3) Injects borated recirculated coolant into the hot legs, during long-term recovery after a LOCA, to reduce the concentration of solids in the reactor core due to evaporation.

(4) Supports the containment pressure boundary.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in the safety analysis and plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The SIS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(2) Provide a flow path for borated water to the RCS during a Fire Safe Shutdown regulated event, which is relied upon to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). Borated water flow is supplied from the RWST or the boric acid storage tanks to the RCS using a CCP via the high head SI flowpath during an alternate shutdown scenario.

2.3.3. Auxiliary Systems

The following systems are addressed in this section:

- Chemical and Volume Control System (2.3.3.1)
- Component Cooling Water System (2.3.3.2)
- Compressed Air and Gas Systems (2.3.3.3)
- Demineralized and Reactor Makeup Water System (2.3.3.4)
- Emergency Diesel Generator and Auxiliary Systems (2.3.3.5)
- Equipment and Floor Drainage Systems (2.3.3.6)
- Fire Protection System (2.3.3.7)
- Plant Ventilation Systems (2.3.3.8)
- Process and Effluent Radiological Monitoring and Sampling System (2.3.3.9)
- Waste Processing Systems (2.3.3.10)
- Spent Fuel Pool Cooling and Cleanup System (2.3.3.11)
- Station Service Water System (2.3.3.12)
- Ventilation Chilled Water Systems (2.3.3.13)
- Potable and Sanitary Water System (2.3.3.14)

2.3.3.1. Chemical and Volume Control System

Description

The purpose of the CVCS is to maintain water levels in the pressurizer and water inventory in the RCS, maintain the seal-water injection flow to RCPs, control reactor coolant water chemistry conditions, activity level, soluble chemical neutron absorber concentration and makeup, provide means for filling, draining and pressure testing the RCS, and support the ECCS.

Performance of the following functions will establish the design criteria of the CVCS:

1. Purification of reactor coolant fluid;
2. Corrosion control;
3. Regulation of reactor coolant inventory;
4. Reactivity shim; and
5. Seal water injection for RCPs.

During power operation, a continuous feed-and-bleed system is maintained to and from the RCS. The bypassed fluid is depressurized, cooled, purified, and stored by a series of valves, heat exchangers, demineralizers, and tanks. Furthermore, the amount of reactor coolant is automatically adjusted to compensate for changes in volume as a result of coolant temperature changes. The CVCS provides reactivity control by varying the boron concentration in the reactor coolant.

Water for the RCP shaft seals is supplied from the charging pump.

The CCPs associated with the CVCS also serve as the high-head pumps for the ECCS. In the event of a LOCA, the CVCS is isolated except for the charging pumps, which inject borated water into the reactor core.

The CVCS consists of several subsystems: The Charging, Letdown and Seal Water System, The Reactor Coolant Purification and Chemistry Control System, The Reactor Makeup Control System, and The Boron Thermal Regeneration System (BTRS). In Addition, The BRS is included with CVCS.

The charging and letdown functions of the CVCS are employed to maintain a programmed water level in the RCS pressurizer, thus maintaining proper reactor coolant inventory during all phases of plant operation. This is achieved by means of continuous feed and bleed process during which the feed rate is automatically controlled based on pressurizer water level. The bleed rate can be chosen to suit various plant operational requirements by selecting the proper combination of letdown orifices in the letdown flow path.

Reactor coolant is discharged to the CVCS from a RCL cold leg; it then flows through the shell side of the regenerative heat exchanger where its temperature is reduced by heat transfer to the charging flow passing through the tubes. The coolant then experiences a large pressure reduction as it passes through the letdown orifice(s) and flows through the tube side of the letdown heat exchanger where its temperature is further reduced. Downstream of the letdown heat exchanger a second pressure reduction occurs. This second pressure reduction is performed by the low pressure letdown valve, the function of which is to maintain upstream pressure thus preventing flashing downstream of the letdown orifices.

The coolant then flows through one of the mixed bed demineralizers. The flow may then pass through the cation bed demineralizer which is used intermittently when additional purification of the reactor coolant is required. Two mixed bed demineralizers may be used in parallel during shutdown for maximum purification.

Alternatively, the flow may be directed such that the mixed bed demineralizers are bypassed. Flow could then be directed to the cation bed demineralizer and/or to the BTRS demineralizer(s) for purification process.

From a point upstream of the BTRS or from a point upstream of the reactor coolant filters, a small sample flow may be diverted from the letdown stream to the Boron Concentration Measurement System. The Boron Concentration Measurement System is abandoned in place.

During reactor coolant boration and dilution operations, especially during load follow (which is not used), the letdown flow leaving the demineralizers may be directed to the BTRS. The coolant then flows through the reactor coolant filter and into the volume control tank through a spray nozzle in the top of the tank. Hydrogen (from the Bulk Hydrogen System) is continuously supplied to the volume control tank where it mixes with fission gasses which are stripped from the reactor coolant into the tank gas space. The contaminated hydrogen is vented to the Gaseous Waste Processing System (GWPS). The partial pressure of hydrogen in the volume control tank determines the concentration of hydrogen dissolved in the reactor coolant for control of oxygen produced by radiolysis of water in the core.

Three pumps (one positive displacement pump and two CCPs) are provided to take suction from the volume control tank and return the cooled, purified reactor coolant to the RCS. Normal charging flow is handled by one of the three charging pumps. This charging flow splits into two paths. The bulk of the charging flow is pumped back to the RCS through the tube side of the regenerative heat exchanger. The letdown flow in the shell side of the regenerative heat exchanger raises the charging flow to a temperature approaching the reactor coolant temperature. The flow is then injected into a cold leg of the RCS. Two charging paths are provided from a point downstream of the regenerative heat exchanger. A flow path is also provided from the regenerative heat exchanger outlet to the pressurizer spray line. An air operated valve in the spray line is employed to provide auxiliary spray to the vapor space of the pressurizer during plant cooldown. This provides a means of cooling the pressurizer near the end of plant cooldown, when the RCPs, which normally provide the driving head for the pressurizer spray, are not operating.

A portion of the charging flow is directed to the RCPs (nominally 8 gpm per pump) through a seal water injection filter. It is directed down to a point between the pump shaft bearing and the thermal barrier cooling coil. Here the flow splits and a portion (nominally 5 gpm per pump) enters the RCS through the labyrinth seals and thermal barrier. The remainder of the flow is directed up the pump shaft, cooling the lower bearing, and to the No. 1 seal leakoff. The No. 1 seal leakoff flow discharges to a common manifold, exits from the containment, and then passes through the seal water return filter and the seal water heat exchanger to the suction side of the charging pumps, or by alternate path to the volume control tank. A very small portion of the seal flow leaks through to the No. 2 seal. A No. 3 seal provides a final barrier to leakage of reactor coolant to the containment atmosphere. The No. 2 leakoff flow is discharged to the reactor coolant drain tank in the Liquid Waste Processing System.

This seal injection flow is assured because there are 3 charging pumps, which individually are capable of providing the normal charging line flow plus the nominal seal injection flow. A No. 3 seal provides a barrier to leakage of reactor coolant to the containment atmosphere. The No. 3 seal injection is supplied by reactor makeup water to a standpipe. Part of the water flows downward, joins with the leakoff from the No. 2 seal and exits through the No. 2 seal leakoff. The remaining water exits through the No. 3 seal leakoff which is discharged to the containment sump.

The excess letdown path is provided as an alternate letdown path from the RCS in the event that the normal letdown path is inoperable. Reactor coolant can be discharged from a cold leg to flow through the tube side of the excess letdown heat exchanger where it is cooled by CCW. Downstream of the heat exchanger a remote-manual control valve controls the letdown flow. The flow normally joins the No. 1 seal discharge manifold and passes through the seal water return filter and heat exchanger to the suction side of the charging pumps. The excess letdown flow can also be directed to the reactor coolant drain tank or directly into the volume control tank via a spray nozzle. When the normal letdown line is not available, the normal purification path is also not in operation. Therefore, this alternate condition would allow continued power operation for a limited period of time, dependent on RCS chemistry and activity. The excess letdown flow path is used to provide additional letdown capability during the final stages of plant heatup. This path removes some of the excess reactor coolant due to expansion of the system as a result of the RCS temperature increase.

Surges in RCS inventory due to load changes are accommodated for the most part in the pressurizer. The volume control tank provides surge capacity for reactor coolant expansion not accommodated by the pressurizer. The volume control tank water level is controlled via a three-way valve which directs letdown/makeup flow to the volume control tank or diverts it to the BRS via the recycle hold-up tank (RHUT). In addition, the three-way valve controller has an “Auto” position which controls the volume control tank water level automatically by diverting all or a portion of the letdown flow to the RHUT when the volume control tank exceeds its normal operating water level. Low level in the volume control tank initiates makeup from the Reactor Makeup Control System. If the Reactor Makeup Control System does not supply sufficient makeup to keep the volume control tank level from falling to a lower level, a low alarm is actuated. Manual action may correct the situation or, if the level continues to decrease, a low-low level signal from both level channels causes the suction of the charging pumps to be transferred to the RWST.

The positive displacement charging pump is also used to perform hydrostatic tests which verify the integrity and leak-tightness of the RCS. The pump can pressurize the RCS to the maximum designated test pressure. The hydrostatic test is performed prior to initial operation and is part of the periodic RCS inservice inspection program.

Mixed bed demineralizers are provided in the letdown line to provide cleanup of the letdown flow. The demineralizers remove ionic corrosion products and certain fission products. During normal power operation one demineralizer is in continuous service and can be supplemented intermittently by the cation bed demineralizer, if necessary, for additional purification. The cation resin removes principally cesium and lithium isotopes from the purification flow. The second mixed bed demineralizer serves as a standby unit for use if the operating demineralizer becomes exhausted during operation. A bypass line and isolation valve also provide additional flexibility for cleanup of letdown flow. The line and valve allow letdown flow to be aligned such that the mixed bed demineralizers are bypassed and flow is directed to the cation bed demineralizer for cleanup. Letdown can also be aligned to flow to the BTRS demineralizer(s) for cleanup, either directly or in series with either a mixed bed or the cation bed demineralizer.

The soluble neutron absorber (boric acid) concentration is controlled by the Reactor Makeup Control System. The BTRS if properly configured, may also be used. The Reactor Makeup Control System is also used to maintain proper reactor coolant inventory. In addition, for emergency boration and makeup, the capability exists to provide refueling water of 4 weight percent boric acid directly to the suction of the charging pump.

The Reactor Makeup Control System provides a manually pre-selected makeup composition to the charging pump suction header or to the volume control tank. The makeup control functions are those of maintaining desired operating fluid inventory in the volume control tank and adjusting reactor coolant boron concentration for reactivity control. Reactor makeup water and boric acid solution (4 weight percent) are blended together at the reactor coolant boron concentration for use as makeup to maintain volume control tank inventory or they can be used separately to change the reactor coolant boron concentration. The boric acid is stored in two boric acid tanks. Two boric acid transfer pumps are provided with one pump normally required to provide boric acid to the suction header of the charging pumps, and the second pump in reserve. They are both aligned to take suction from separate boric acid tanks. On a demand signal by the reactor makeup controller, the pump starts and delivers boric acid to the suction header of the charging pumps. The pump can also be used to recirculate the boric acid tank fluid.

All portions of the CVCS which normally contain concentrated boric acid solution (4 weight percent boric acid) are required to be located within a heated area in order to maintain solution temperature at ≥65°F. If a portion of the system which normally contains concentrated boric acid solution is not located in a heated area, it must be provided with some other means (e.g., heat tracing) to maintain solution temperature at ≥65°F. Heat tracing is utilized inside the plant on 4 percent boric acid solution lines where potential freezing poses a recrystallization problem.

The reactor makeup water pumps (RMWPs) take suction from the reactor make-up water storage tank and are employed for various makeup and flushing operations throughout the systems. There is one pump for each unit plus a common pump for both units. One of these pumps normally operates continuously and provides flow to the suction header of the charging pumps or the volume control tank through the letdown line and spray nozzle on demand.

During reactor operation, changes are made in the reactor coolant boron concentration for the following conditions:

1. Reactor startup – boron concentration must be decreased from shutdown concentration to achieve criticality.

2. Load follow – boron concentration must be either increased or decreased to compensate for the xenon transient following a change in load.

3. Fuel burnup – boron concentration must be decreased to compensate for fuel burnup and the buildup of fission products in the fuel.

4. Cold shutdown – boron concentration must be increased to the cold shutdown concentration.

5. Burnable Poison depletion – dependent on the core design and time in core life. Boron concentration may need to be increased to compensate for the depletion of burnable poisons in the fuel.

The BTRS may be used to control boron concentration to compensate for xenon transients during load follow operations. Boron thermal regeneration can also be used in conjunction with dilution operations of the Reactor Makeup Control System to reduce the amount of effluent to be processed by the Liquid Waste System or the BRS.

The boron thermal regeneration process was designed to allow load follow operations as required by the design load cycle. Load follow operation is currently not utilized at Comanche Peak.

Because load follow operation is currently not utilized, there is no need for chilled water to be provided to the letdown chiller heat exchanger. Therefore, the BTRS chiller and associated components in the chilled water loop are normally removed from service and drained so as not to provide chilled water to the shell side of the letdown chiller heat Exchanger. Also, because load follow operation is currently not utilized, the heating source for the letdown reheat heat exchanger is normally isolated, and the tube side of the heat exchanger is drained. There is no near-term plan to utilize these components for load follow operation. If the BTRS chiller and associated components are ever returned to service, flow to and from the thermal regeneration demineralizers and piping vibration will be verified prior to the return to service.

The BTRS is currently used to reduce reactor coolant boron concentration at the end of the core cycle. Additionally, the BTRS demineralizers may be loaded with various types of resin in order to provide supplemental or enhanced cleanup of CVCS letdown flow.

When the BTRS is placed in service, BTRS water taken from the RCS may flow through the tube side of the letdown chiller heat exchanger, as well as through the shell side of the letdown reheat heat exchanger. There is the possibility for leakage of water containing radioactivity from the tube side into the normally drained shell side of the letdown chiller heat exchanger, or from the shell side into the normally drained tube side of the letdown reheat heat exchanger.

Leakage into the shell side of the letdown chiller heat exchanger passes through to the chiller surge tank. The high-level alarm of the chiller surge tank provides in-leakage detection when the BTRS is in service. Leakage water entering the tube side of the letdown reheat heat exchanger passes through open drain valves into floor drains which direct the water to floor drain tanks 1 and 2, both of which have high level alarms.

Downstream of the mixed bed demineralizers, the letdown flow can be diverted to the BTRS where part or all of the letdown flow can be treated when boron concentration changes are desired.

Additionally, the BTRS demineralizer(s) can be utilized to provide for supplemental or enhanced cleanup of letdown flow. After processing, the flow is returned to a point upstream of the reactor coolant filter.

Storage and release of boron during load follow operation is determined by the temperature of fluid entering the thermal regeneration demineralizers. A chiller unit and a group of heat exchangers are employed to provide the desired fluid temperatures at the demineralizer inlets for either storage or release operation of the system.

The flow path through the BTRS is different for the boron storage and the boron release operations. During boron storage, the letdown stream enters the moderating heat exchanger and from there it passes through the letdown chiller heat exchanger. These two heat exchangers cool the letdown stream prior to it entering the demineralizers. The letdown reheat heat exchanger is valved out on the tube side and performs no function during boron storage operations. The temperature of the letdown stream at the point of entry to the demineralizers is controlled automatically by the temperature control valve which controls the shell side flow to the letdown chiller heat exchanger. After passing through the demineralizers, the letdown enters the moderating heat exchanger shell side, where it is heated by the incoming letdown stream before going to the volume control tank.

Therefore, for boron storage, a decrease in the boric acid concentration in the reactor coolant is accomplished by sending the letdown flow at relatively low temperatures to the thermal regeneration demineralizers. The resin, which was depleted of boron at high temperature during a prior boron release operation, is now capable of storing boron from the low temperature letdown stream. Reactor coolant with a decreased concentration of boric acid leaves the demineralizers and is directed to the RCS via the charging system.

During the boron release operation, the letdown stream enters the moderating heat exchanger tube side, bypasses the letdown chiller heat exchanger, and passes through the shell side of the letdown reheat heat exchanger. The moderating and letdown reheat heat exchangers heat the letdown stream prior to it entering the resin beds. The temperature of the letdown at the point of entry to the demineralizers is controlled automatically by the temperature control valve which controls the flow rate on the tube side of the letdown reheat heat exchanger. After passing through the demineralizers, the letdown stream enters the shell side of the moderating heat exchanger, passes through the tube side of the letdown chiller heat exchanger, and then goes to the volume control tank. The temperature of the letdown stream entering the volume control tank is controlled automatically by adjusting the shell side flow rate on the letdown chiller heat exchanger. Thus, for boron release, an increase in the boric acid concentration in the reactor coolant is accomplished by sending the letdown flow at relatively high temperatures to the thermal regeneration demineralizers. The water flowing through the demineralizers now releases boron which was stored by the resin at low temperature during a previous boron storage operation. The boron enriched reactor coolant is returned to the RCS via the charging system.

The purpose of the BRS is to reuse reactor coolant effluent by decontaminating it using demineralization and gas stripping and then using evaporation to separate and recover boric acid and makeup water.

The BRS collects and processes effluent which may be reused as makeup to the RCS. For the most part, this effluent is the deaerated, tritiated, borated, and radioactive water from the letdown and process drains. The operation of BRS is not continual and only operates in batches, once it has collected effluent from core cycles.

When water is directed to the BRS, the flow passes first through the recycle evaporator feed demineralizers and filters and then into the RHUTs. The recycle evaporator feed pumps can be used to transfer liquid from one RHUT to the other if desired. When sufficient water is accumulated to warrant evaporator operation, the recycle evaporator feed pumps take suction from the selected RHUT. The fluid then flows through the recycle evaporator. Here, dissolved gases (i.e., hydrogen, fission gases and other gases) are removed in the stripping column before the liquid enters the evaporator shell.

These gases are directed to the evaporator vent condenser and then to the Plant Ventilation System. An alternate flow path to the Gaseous Waste Processing System is available. During evaporator operation, distillate from the evaporator flows to the waste monitor tanks for discharge. Also located in this flow path, are the recycle evaporator condensate demineralizer and the recycle evaporator condensate filter. The accumulated batch is normally transferred directly to the boric acid tanks in the CVCS through the recycle evaporator concentrates filter. Before transferring the boric acid from the evaporator to the boric acid tanks, it is analyzed, and, if it does not meet the required chemical standards, it can be diverted back to the RHUTs for reprocessing or to the Liquid Waste Processing System for disposal.

<u>Boundary</u>

The CVCS boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0253-LR
- M1-0253-A-LR
- M1-0254-LR
- M1-0255-LR
- M1-0255-01-LR
- M1-0255-02-LR
- M1-0256-LR
- M1-0256-A-LR

Unit 2:

- M2-0253-LR
- M2-0253-A-LR
- M2-0254-LR
- M2-0255-LR
- M2-0255-01-LR
- M2-0255-02-LR
- M2-0256-A-LR
- M2-0256-B-LR

Common:

- M1-0257-LR
- M1-0258-LR
- M1-0259-LR
- M1-0259-01-LR
- M1-0259-A-LR

The portion of the CVCS subject to AMR begins at the interface between the RCS and attached Class 1 piping to the Class 2 boundaries. CVCS letdown begins off of RCS loop 3. The Class 1 CVCS piping is included with the RCS and Attached Piping System, found in Section 2.3.1.3, such that the CVCS boundary begins at the

Class 2 piping at the Class 1/Class 2 boundary. The RCS and Attached Piping System interfaces with CVCS charging in a similar way, where CVCS charging lines include Class 2 piping and the Class 1 piping is part of the RCS and Attached Piping System, which is discussed in Section 2.3.1.3. Normal charging goes to RCS loop 4 and alternate charging goes to RCS loop 1. CVCS auxiliary spray following CVCS charging interfaces with RCS pressurizer spray lines for loops 1 and 4. The CVCS and RCS interface at the RCP where the CVCS supplies seal water injection flow. In addition, CVCS provides water for seal #3 injection standpipes, and receives reactor coolant from seal 1, 2 and 3 leakoff lines. Seal 1 leakoff is sent to the CVCS volume control tank. Seal 2 leakoff interfaces with the Liquid Radioactive Waste System where it is routed to the reactor coolant drain tank (RCDT). Seal 3 leakoff is sent to the Equipment And Floor Drainage System.

The RHUT in the CVCS is located in the Auxiliary Building (AB). The tanks are located in a watertight compartment which drains to Sump 8 through normally locked-closed valves. The RHUT vent ejector is addressed in Table 3.3.2-1.

The RCS and attached Class 1 piping boundary ends at

- Fail closed valve to regenerative heat exchanger;
- Check valves downstream of regenerative heat exchanger;
- Fail closed valve from Regenerative heat exchanger to the RCS and attached piping;
- Fail closed valve from RCS loop 1 excess letdown to excess letdown heat exchanger;
- RCP seal 1 housing;
- RCP seal water injections at various check valves;
- RCP seal bypass orifices; and
- RCS flow restrictors (Class 1/Class 2).

The Boron Concentration Measurement System, which is abandoned in place, is classified as non-safety affecting safety because it is conservatively assumed to be filled with liquid during normal operation. The system consists of piping and piping components.

The chemical mixing tank is NNS and is directly connected to nuclear safety related Class 2 and 3 piping.

The letdown chiller heat exchanger shell side is supplied by a closed cooling water system and is a nuclear safety related component. The chiller unit, which provides the cooling is considered a non-safety affecting safety component. The chiller is considered a complex assembly for AMR with the exception of the chiller evaporator and condenser heat exchangers. In the event the letdown chiller fails to cool the liquid, such that the BTRS cannot be used, the Reactor Makeup Control System of the CVCS can be used for alternate boration and dilution of reactor coolant for load follow.

The chiller pumps deliver cooling fluid. If one pump fails, the other provides the necessary flow of fluid for chiller unit operation. The pumps are located in the AB and are NNS.

The chiller surge tank contains the coolant system inventory and provides the water source for the chiller pumps. This tank is also NNS and located in the AB.

The boric acid batching tank is Class 5 NNS and is attached to nuclear safety related Class 3 piping. It is also located in the AB near other nuclear safety related components; therefore, it is within the scope of LR.

The recycle evaporator feed demineralizer is in its own room in the AB and is included within the scope of LR.

The recycle evaporator feed pumps are NNS and contain liquid during normal operation and so are included in the evaluation boundary.

The BRS recycle evaporator package (TBX-BREVRE-01) is in operation during evaporator operation and contains nuclear safety related components as well as NNS:

- Feed preheater (both feed and steam sides) is NNS;
- The submerged tube evaporator (both feed and steam sides) is NNS;
- Evaporator condenser distillate water side is NNS, but the cooling water side (channel head) is Class 3;
- Recycle distillate cooler distillate side is NNS and the cooling water side (shell side) is Class 3;
- Vent condenser gas side is NNS, and the cooling water side (channel head) is Class 3;
- Distillate and concentrate pumps are NNS;
- Feed, distillate, concentrate, and vent piping and valves are all NNS, but CCWS piping and valves are Class 3; and
- Class 5 piping and supports are NNS, and valves are NNS.

The CVCS CCPs are a part of the ECCS boundary. Also, in the ECCS flow path are the SI pumps, RWST, RHR pumps and heat exchangers, accumulator tanks, and the RCS cold legs (FSAR Figure 6.3-2). Included in this scoping boundary are the minimum flow recirculation lines from each of the CCP discharge lines. The minimum flow recirculation lines join together and return to the volume control tank through the seal water heat exchanger. The scoping boundary for the positive displacement charging pump also includes the recirculation line and the discharge relief valve line. Included in the CVCS scoping boundary for the high-pressure injection flow path is the piping downstream of the isolation valves from the A-train RHR low-pressure injection pump discharge. Also included in this scoping boundary is the portion of the charging pump to SI pump suction header which begins downstream of the SIS at the motor-operated suction cross-connect isolation valves.

The normal (non-emergency) flow path for the CVCS scoping boundary begins at the RCS and attached piping interfaces. This is the letdown flow path which includes flow through the regenerative heat exchanger, excess letdown heat exchanger, letdown heat exchanger and mixed bed and cation bed demineralizers. The flow continues through the volume control tank and through the suction supply line to the charging pump suction header and the CCPs and positive displacement charging pump. The scoping boundary continues through the discharge line for the charging pumps supplying the seal injection and makeup flow, and divides into two lines: the first line supplying seal injection flow to the RCPs, and the second line supplying flow to the makeup line connections on the RCL cold legs or pressurizer auxiliary spray line.

The scoping boundary for the boric acid addition portion of the system begins at the boric acid tanks, continues through the boric acid transfer pumps to the boric acid blender and terminates at the volume control tank. The scoping boundary includes the minimum flow line for the boric acid transfer pumps back to the boric acid tanks and the line from the boric acid batching tank to the suction of the boric acid transfer pumps. The scoping boundary continues to the upstream side of the isolation valve that supplies boric acid to the RWST.

The scoping boundary for the BRS includes tanks (RHUTs), pumps (recycle evaporator feed), filters (recycle evaporator condensate, recycle evaporator feed, and recycle evaporator concentrates), recycle evaporator sample coolers, demineralizers (recycle evaporator condensate and boron recycle evaporator feed), and the recycle evaporator package.

The scoping boundary for the BRS begins at the recycle evaporator feed demineralizers and recycle evaporator feed filters, to the RHUTs and continues to the suction header of the recycle evaporator feed pumps, continues through the pumps to a common discharge line to the recycle evaporator condensate demineralizer. Flow from the recycle evaporator feed pumps could be routed through the boric acid processing recycle evaporator packages and returned to the common pump discharge line upstream of the recycle evaporator condensate demineralizer. The SIS pressure relief, VCT relief, CCPs suction relief and positive displacement charging pump suction relief are routed to the RHUTs in the BRS.

The RHUTs are NNS and are not included within the scope of LR because the tanks are located in watertight compartments which do not house nuclear safety related components. The upper level (platform grating) of the tank rooms contain nuclear safety related CCW lines and cabling routed within rigid steel conduit; however, there is reasonable assurance that a leak from the tank would be detected and corrective actions taken prior to loss of intended function of the nuclear safety related components. Reasonable assurance is based on preventive maintenance (PM) activities which have personnel periodically entering the rooms.

The scoping boundary for the BTRS begins at the inlet piping to the moderating heat exchanger, continues through the tube side of the moderating heat exchanger, through the tube side of the letdown chiller heat exchanger, and through the shell side of the letdown reheat heat exchanger. Downstream of these heat exchangers, the scoping boundary for the BTRS continues through the boron thermal regeneration demineralizers, to the shell side of the moderating heat exchanger. The scoping boundary continues from the shell side of the moderating heat exchanger and ends at the moderating heat exchanger to reactor coolant filter isolation valve upstream of the reactor coolant filter. This portion of the BTRS also includes the chiller surge tank, two chiller pumps, and boron thermal regeneration chiller, which provides the cooling on the shell side of the letdown chiller heat exchanger. The letdown reheat heat exchanger tube side is normally removed from service, isolated and drained. When in service, both the shell and tube side each have borated reactor coolant water environments from and to the CVCS letdown path.

All associated piping, components, and instrumentation contained in the above described flow paths, necessary for performance of their design function are included in the system evaluation boundary.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide RCPB. The CVCS has connections to the RCS on the cold legs and RCP seals through a series of check valves;

(2) Achieve and maintain the reactor core subcritical for any mode of normal operation or event. The CVCS injects borated water into the RCS for emergency core cooling, and provides for chemical conditioning of the RCS for reactivity control under normal operating conditions;

(3) Introduce emergency negative reactivity to make the reactor subcritical. The CVCS injects borated water into the RCS for emergency core cooling, and provides for chemical conditioning of the RCS for reactivity control under normal operating conditions;

(4) Provide and maintain sufficient reactor coolant inventory for the RCS for core cooling. The CVCS injects borated water into the RCS from the RWST for emergency core cooling;

(5) Introduce negative reactivity. The CVCS injects borated water into the reactor coolant and provides for chemical conditioning of the RCS for reactivity control under normal operating conditions;

(6) Provide primary containment boundary. The CVCS have piping connections penetrating the primary containment and valves that provide the containment isolation function; and

(7) Maintain the dose consequences within the guidelines of 10 CFR 50.67 or 10 CFR Part 100. The CVCS maintain adequate reactor coolant inventory in

the reactor vessel to limit core damage. The CVCS ensure that there is no significant reduction in shutdown margin when cooling water is introduced into the reactor, which ensures that radioactive releases are satisfied for the offsite dose criteria.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The CVCS provides borated water to the RCP seals for an Appendix R fire.

(2) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The CVCS provides indication and controls to mitigate the consequences of DBEs utilizing equipment in the Environmental Qualification of Electric Components (B.2.2.2) AMP.

(3) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63). The CVCS are designed to mitigate the consequences of a SBO by providing seal water flow to the RCP seals.

2.3.3.2. Component Cooling Water System

Description

The purpose of the CCW System is to transfer heat from nuclear safety related structures, systems, and components to an ultimate heat sink (UHS) within a closed loop. The closed loop also provides an intermediate barrier between radioactive or potentially radioactive sources, thus precluding direct leakage of radioactive fluids into the UHS SSI.

The CCW System supplies adequate cooling water to remove heat from the components which are part of the RCS, ECCS, CSS, CVCS, SFP Cooling and Cleanup System, Waste Processing System, Sampling System, Safety Chilled Water System, NNS ventilation chillers (condensers) and the Instrument Air System during all required operating modes and transfers the heat to the Station Service Water (SSW) System.

The CCW System consists of two redundant safeguards loops and one non-safeguards loop (per unit). The safeguards loops service the engineering safeguards components and the non-safeguards loop services the NNS portions of the system. The system is sized for the full capacity cooling requirements of the unit during all postulated plant operating modes. Each safeguards loop consists of one (1) 100 percent capacity CCW pump and heat exchanger. The non-safeguards loop is supplied by either safeguards loop. During normal plant operation, one pump and heat exchanger are in operation and the second pump and heat exchanger are on standby. The Unit 1 and 2 safeguards loops are isolated from each other during normal operation by at least one locked closed isolation valve.

Each safeguards loop supplies and returns cooling to/from the following:

1. Two containment spray pump seal coolers
2. One RHR pump seal cooler
3. One RHR heat exchanger
4. One containment spray heat exchanger
5. One Chilled Water System condenser
6. Two control room A/C condensers (common)

7. One uninterruptible power supply A/C condenser (common)

8. One Post-Accident-Sample System (PASS) sample cooler (Train-A only)

The Unit 1 and 2 safeguards loops are isolated from their non-safeguards loops in abnormal conditions where loss of inventory occurs by redundant automatic isolation valves.

The non-safeguards loop consists of:

1. Two hydrogen recombiner heat exchangers (common)

2. Two waste gas compressor seal water coolers (common)

3. Process sample coolers (NNS)

4. One positive displacement charging pump hydraulic coupling oil cooler and lube oil cooler

5. One letdown heat exchanger (CVCS letdown cooling)

6. One seal water heat exchanger (CVCS, RCPs seals)

7. Two SFP heat exchangers (common)

8. One boron recycle evaporator package (not used) consisting of one distillate cooler, one evaporator condenser, and one vent condenser (common)

9. One waste evaporator package (not used) consisting of one distillate cooler, one evaporator condenser, and one vent condenser (common)

10. One floor drain evaporator package (not used) consisting of one distillate cooler, one evaporator condenser and one vent condenser (common)

11. Four RCP coolers, each consisting of one lower bearing lube oil cooler, one upper bearing lube oil cooler, two motor air coolers, and one thermal barrier cooler (located inside containment)

12. One excess letdown heat exchanger (CVCS equipment located inside containment) and one reactor coolant drain tank heat exchanger

13. Four ventilation chillers (NNS) (common)

14. One letdown chiller package condenser (NNS) (not used)

15. Two instrument air compressors

16. One in-line trim cooler (Unit 1) and two in-line trim coolers (Unit 2)

17. One filter demineralizer chemical addition skid consisting of demineralizer, filter, hydrazine tank and metering pump

The two safeguards loops are redundant, in that the components supplied with cooling water by either of the safeguards loops can perform the minimum required safeguards functions.

Two cooling water supply lines from the non-safeguards loop penetrate the corresponding unit's containment structure. One line supplies cooling water to the RCPs and the other line supplies cooling water to the excess letdown heat exchanger and reactor coolant drain tank heat exchanger. Three cooling water return lines penetrate the containment structure: one line from the excess letdown and reactor coolant drain tank heat exchangers; one line from the RCPs bearing lube oil coolers and motor air coolers and the third from the RCP thermal barrier coolers. The containment isolation valves on this third penetration are designed to close automatically upon a detection of in-leakage of reactor coolant to the CCW System. The sixth CCW containment penetration is for the discharge piping from the CCW containment drain tank pumps to the CCW drain tank in the SGB.

There are no containment penetrations directly associated with the CCW System safeguards loops.

The non-safeguards loops are cross-connected to permit either unit to supply cooling water to common ventilation chillers, evaporator packages, hydrogen recombiners, and waste gas compressors. These components are separated from the CCW of the other unit by at least one closed valve. The non-safeguards loops are also provided with cross-connections between the two SFP heat exchangers which are isolated by CCW butterfly valves so that either spent fuel heat exchanger can be cooled by either Unit's CCW. Cross-connections in the SFP Cooling and Cleanup System ensure that at least one spent fuel (SF) pump can be aligned to either heat exchanger, if required. Alternatively, the CCW butterfly valves may be reoriented for flow-through operation.

There are two CCW surge tanks; one for each unit. The surge tanks are horizontal cylindrical tanks. The surge tanks are located in the AB at an elevation which assures adequate available NPSH to the CCW pumps and is the highest point in the system. The surge tanks are vented to the AB atmosphere. Each surge tank is partitioned to provide a separate chamber and separate piping for each loop (Train A and B).

The system hydraulics during single CCW pump operation causes water to overflow the surge tank partition to the surge tank chamber on the suction-side of the operating pump. A 3-ft long by 6-in high rectangular hole is cut in the surge tank partitions to allow this flow without affecting the surge tank level alarms and control functions. The partitions have this opening added above the "empty" level to equalize level on both sides of the tank. Therefore, the separation of volumes is limited to below this opening.

To preclude discharging corrosion-inhibited component cooling and chilled water to the environment, one drain tank for each unit is provided in the SGB to collect CCW from piping and equipment being drained and from the discharge of most of the CCW thermal relief valves. Drainage flows to the drain tank by gravity. Two 100 percent-capacity CCW System drain pumps are provided. Discharge lines from some CCW thermal relief valves and overflow lines from the CCW System surge tank are routed to the floor drains.

One CCW System drain pump from each unit is used to pump the drains to the truck discharge connection, or to the Wastewater Management System, depending on the quality and quantity of the water collected.

One containment CCW System drain tank for each unit is provided to collect CCW from components in the containment. Two 100- percent-capacity containment CCW System drain pumps are provided. One pump for each unit is used to pump the drains back to the main drain tank in the SGB. One containment penetration is provided for the drain line.

The CCW System water chemistry is controlled via a filter/demineralizer/chemical addition skid (one per Unit) and by the addition of chemicals via the CAT. Samples are periodically taken from sample taps to verify that water chemistry is as required. If dilution is required, water is bled off to the drain tank through one of the existing drain connections. Noninhibited water is added through the CCW System surge tank.

Boundary

The CCW System boundaries for LR are reflected on the LRBDs listed below.

Nuclear safety related components in the CCW System are those that maintain the pressure boundary of the system starting from the CCW surge tanks and continuing through the CCW pumps and the CCW heat exchangers (including all associated piping, valves, and other components).

The CCW System interfaces with various nuclear safety related and NNS systems. Therefore, the CCW System boundaries for LR extend to and through the interface with these different systems (interfacing heat exchangers/coolers and other components) and extends back to the CCW surge tanks. The CCW System components include all nuclear safety related components up until the inlet and outlet piping, piping components, instrumentation and valves associated with the interfacing mechanical components (such as heat exchangers/coolers) for each of these interfacing systems as listed on the CCW System LRBDs. These individual cooling units or heat exchangers and other major components supplied by the CCW System are evaluated in their specific systems.

The CCW System boundary interface with other interfacing systems that are not associated with heat exchangers/coolers directly supplied by the CCW System such as the SSW and the ECCS include all nuclear safety related components up to the extent indicated on the CCW System LRBDs.

Also included in the CCW System are portions of the NNS piping and equipment on the LRBDs.

Equipment included as part of the NNS components with a leakage boundary (spatial) function include the CCW drain tanks, the CATs, the enclosure of the instrument air compressor packages, the components on the filter demineralizer chemical addition skid, the containment CCW drain tanks and the CCW drain pumps. Equipment included as part of the NNS components with a leakage boundary (spatial) and structural integrity (attached) function include the piping and valves that extend beyond the nuclear safety related/NNS interfaces up until the NNS components listed above.

The NNS components with a leakage boundary (spatial) and structural integrity (attached) function also includes the piping that extend beyond the nuclear safety related/NNS interface up to the ventilation chillers, the seal water coolers (associated with the waste gas compressor packages) and the catalytic recombiner package heat exchangers.

Additionally, one of the CCW trim cooler installed on Unit 2 and associated piping and valves, are also included as part of the NNS components with a leakage boundary (spatial) function. Other CCW Trim Coolers installed in Unit 1 and 2, along with associated piping and valves (as shown on the CCW System LRBDs), are located within the Turbine Building and are therefore not included within the scope of LR.

- M2-0231-LR
- M2-0231A-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The CCW System removes heat from nuclear safety related SSCs and transfers it in a closed loop to the SSW, where it is transferred to an UHS SSI, under normal operating and accident conditions.

(2) The CCW System is required to remove residual heat from the RCS.

(3) The CCW System supplies cooling water to the CVCS let down heat exchangers to cool the letdown flow to the CVCS.

(4) The CCW System also functions to support and maintain the containment pressure boundary. A leakage of the reactor coolant to the CCW System is detected by monitoring the level of the CCW surge tank. Additionally, the CCW System also consists of radiation monitors and valves that detect and isolate any leakage of reactor coolant into the CCW System.

(5) The closed loop of the CCW System provides an intermediate barrier between radioactive or potentially radioactive sources, thus precluding direct leakage of radioactive fluids into the UHS (SSI).

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Contains components relied upon to perform a function that demonstrates compliance with regulations for EQ (10 CFR 50.49). The CCW System includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(2) Provides cooling for required components during Fire Safe Shutdown regulated events (10 CFR 50.48) and SBO (10 CFR 50.63) regulated events.

2.3.3.3. Compressed Air and Gas Systems

Description

Compressed Air System

The Compressed Air System (CAS) consists of two separate systems, the Instrument Air System (CI) and the Service Air System (CA). The CI is designed to provide a reliable supply of clean, dry, oil-free air of suitable quality and pressure for pneumatic instruments and controls and pneumatically operated valves for normal plant operation. The CA is designed to provide the necessary compressed air for pneumatic tools and general plant usage. The CI, via a filtering skid, also provides suitable air to inflate the refueling lift gate seals. The CAS is in scope for LR; however, there are portions of the CAS that do not perform intended functions and are not in scope.

The CAS serves no safety function because it is not required to achieve safe shutdown or to mitigate the consequences of a DBA. Therefore, the CAS is a NNS system, however, the lines penetrating containment are designed in accordance with NRC GDC 2, 4, 5, and 56, NRC RGs 1.26 and 1.29, and applicable BTPs.

Instrument Air System

During normal system operation, instrument air to each unit is supplied by a train of equipment consisting of a lead instrument air compressor package, air receiver, and air dryer package. Two complete common standby train packages are available and automatically come online if the unit compressors cannot maintain header pressure. The common compressors can be manually selected as the lead or backup compressor for either unit.

Before being delivered to the distribution network, the instrument air is filtered, dried, and filtered again.

The instrument air line, that penetrates the containment is provided with two isolation valves. In addition, a flow-limiting orifice is provided for the penetration.

A pressure control valve and local supply station are provided for the refueling gates in the FB.

Air-operated valves throughout the plant are arranged for safe failure in the absence of air.

Accumulators are provided for the auxiliary feedwater control valves, recirculation valves, steam admission valves, and atmospheric relief valves. Accumulators are also provided for each Steam Generator PORV/atmospheric relief valve, and the CCW return pressure controller for the safety chillers. Accumulators are also provided for the control room air inlet control dampers. The accumulators themselves are considered as part of the system which they supply and are evaluated in those systems. However, instrument air lines to these accumulators are within the scope of this system, including Safety Class 3 portions.

Service Air System

During normal operation, service air to each unit is supplied by a service air compressor and a service air receiver. The service air is then delivered to the distribution system. The service air line that penetrates the containment is provided with two isolation valves. In addition, a flow limiting orifice is provided for the penetration.

A pressure control valve and local supply station is provided for the refueling gate in each RCB.

Plant Gas System

The Plant Gas System consists of the Nitrogen Gas Supply System (NGS), the Oxygen Gas Supply System (OGS), the Hydrogen Gas Supply System (HGS), the Miscellaneous Gas Supply System (XGS), and the Argon Gas Supply System (CGS). The Plant Gas System is within the scope of LR. However, portions of the system are not required to perform intended functions and are not in scope. The only portions of the system that are required to perform intended functions are the NGS and HGS.

Nitrogen Gas Supply System

The NGS is designed to provide storage capacity to ensure regular replenishment of consumed nitrogen. The system is divided into two separate, permanent subsystems: the bulk storage supply and the bottle supply. Each of these subsystems has two supply manifolds, one for normal operation, the other to act as a standby source.

Nitrogen is supplied to various components from a 2400 psig pressure Bulk Storage System or bottle supply.

The low pressure portion of the Bulk Storage System supplies nitrogen gas as a cover gas (for intermittent use) to multiple components, including the auxiliary feedwater CST, CVCS volume control tank, RCS PRT, reactor makeup water storage tank.

The high-pressure portion of the Bulk Storage System supplies nitrogen (for intermittent use) to the SIS accumulators and pressurizer PORVs. This portion of the system is not in scope and is outside LR evaluation boundaries.

Nitrogen bottle supply provides a permanent source of nitrogen to the containment air and reactor coolant PASS remote operating modules for sample line purging to allow for continuous operation of PASS when needed. This portion of the system is not in scope and is outside LR evaluation boundaries.

The piping for the NGS is NNS, except for those portions which connect to a nuclear safety related component or penetrate the containment. Where this piping does connect to a nuclear safety related component requiring an isolation valve, this valve and the piping between the valve and the connection are designed to the same safety class as the component. Lines which do not require isolation valves are NNS up to the connection of the nuclear safety related component. Note: NGS lines which penetrate containment or connect to a nuclear safety related component are considered as part of the system which they supply, as shown on applicable LRBDs, and are evaluated under those systems.

Hydrogen Gas Supply System

The HGS is designed to provide bulk gas storage capacity to ensure regular replenishment of consumed gases. The system has two manifolds, one for normal operation, the other for standby reserve.

Hydrogen is supplied via bulk gas supply or bottle gas supply. Bulk gas supply supplies the volume control tanks. The HGS supplies a header which is common to the two units. This header divides into the NSSS supply line and the turbine generator supply line. The NSSS supply line supplies each unit's volume control tank. Bulk gas supply also supplies the gas decay tanks, turbine generator, and primary water tank. However, these portions of the system are not in scope and are outside LR evaluation boundaries.

Hydrogen bottled gas supply (HBS) supplies the turbine generator and primary water tank, as well as the reactor coolant drain tank. This portion of the system is not in scope and is outside LR evaluation boundaries.

The piping for the HGS is NNS except for those portions which connect to a nuclear safety related component or penetrate the containment. Where this piping does connect to a nuclear safety related component requiring an isolation valve, this valve and the piping between the valve and the connection are designed to the same safety-class as the component. Note: hydrogen supply lines which penetrate containment or connect to a nuclear safety related component are considered as part of the system which they supply, as shown on applicable LRBDs, and are evaluated under those systems.

For additional description of the Plant Gas System and its components, see FSAR Section 10.4.15.

<u>Boundary</u>

The LR boundaries are reflected on the LRBDs listed below.

CAS scoping boundaries include CI connections to air accumulators as shown on LRBDs M1-0216-001-LR, M1-0218-001-LR, M1-0218-001A-LR, M2-0218-001-LR, and M2-0218-002-LR.

Additional CAS scoping boundaries include CI and CA containment penetrations, as shown on LRBDs M1-0216-A-LR, M1-0218-LR, M2-0216-A-LR, M2-0216-B-LR, and M2-0218-LR.

Final CAS scoping boundaries are CI System connections to the SFP swing gate seals, as shown on M1-0219-LR.

Plant Gas System scoping boundaries include HG supplies to CVCS volume control tanks, as shown on LRBDs M1-0243-002-LR and M2-0243-002-LR.

Additional Plant Gas System scoping boundaries include NGS supplies to the CVCS volume control tanks and boric acid tanks, RCS PRTs, demineralized water reactor makeup water storage tanks, and CSTs, as shown on LRBDs M1-0243-A-LR and M2-0243-A-LR.

Unit 1:

- M1-0243-002-LR

Unit 2:

- M2-0216-A-LR
- M2-0216-B-LR
- M2-0218-LR
- M2-0218-001-LR
- M2-0218-002-LR
- M2-0243-A-LR
- M2-0243-002-LR

Common:

- M1-0219-LR

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Support containment pressure boundary. The CAS includes piping that penetrates the containment. The containment penetrations, including containment isolation valves, are relied upon to ensure containment integrity.

(2) Prevent loss of shielding and cooling water for stored fuel and spent fuel. The CAS supplies SFP refueling gate seals to prevent leakage of pool water.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). CAS containment isolation valves and swing gate seal pressure indicators are included in the scope of the Environmental Qualification of Electric Components (B.2.2.2) AMP.

2.3.3.4. Demineralized and Reactor Makeup Water System

Description

The Demineralized and Reactor Makeup Water System (DRMWS) is used to supply demineralized water to various nuclear safety related and NNS related systems. The DRMWS is comprised of two subsystems: the demineralized water subsystem and the RMW subsystem.

A demineralized water subsystem is provided to furnish deaerated and non-deaerated demineralized water to both units. The system consists of one demineralized water storage tank, two demineralized water transfer pumps, two vacuum deaerator feed pumps, one vacuum deaerator, two vacuum deaerator vacuum pumps, one duplex condensate return unit, two deaerated water transfer pumps and all associated piping, valves, instrumentation, and controls.

The demineralized water storage tank receives non-deaerated makeup water from the water treatment system through a modulating level control station. The demineralized water storage tank is a 400,000-gallon plastic lined carbon steel atmospheric tank located in the yard. Two demineralized water transfer pumps take suction from the demineralized water storage tank.

A RMW subsystem is designed to furnish reactor grade deaerated demineralized makeup water to each unit.

Each unit has one reactor makeup water storage tank (RMWST), one reactor makeup water pump (RMWP) (one redundant RMWP is shared by both units) and all associated piping, valves, instrumentation, and controls.

The RMWST of each unit receives makeup from the deaerated water transfer pumps through a level control station. The reactor makeup water storage tanks are steel reinforced concrete atmospheric tanks lined with stainless steel and equipped with a diaphragm. Nitrogen gas is supplied from bulk storage as required to the RMWST to prevent oxygen rich air from reaching the water. Maximum nitrogen flow rate into the RMWST is controlled by an inlet restricting orifice. Nitrogen is maintained between the tank wall and the diaphragm to ensure the diaphragm does not adhere to the tank wall and is able to freely move during tank drawdown during a postulated DBE. The RMWST has the capability for nitrogen sparging through the normal recirculation flow path. Nitrogen pressure is maintained by a diaphragm (flapper) valve at the terminus of the vent pipe.

Three RMWPs take suction from the reactor makeup water storage tanks. During normal operation, one RMWP is aligned with a reactor makeup storage tank to supply deaerated demineralized water to a single unit (one pump per unit). The third pump is used as a redundant standby pump for each unit which is normally isolated from each unit's flow paths by manual isolation valves.

Flow restriction orifices are provided to limit flow rates to the CVCS and CCW System/CHS.

<u>Boundary</u>

The DRMWS boundaries for LR are reflected on the LRBDs listed below.

The DRMWS includes those nuclear safety related components starting at the RMWST that supply treated water to other nuclear safety related systems as described above. The RMWST diaphragm is included in scope, since, if degraded, could block the ability to makeup to nuclear safety related systems. Piping that provides a pressure boundary for the RCB at containment penetrations is also in scope. Other piping and components that are associated with class 5 components and are in Seismic Category I structures that are normally filled with water are also in scope. These have a leakage (spatial) intended function corresponding to the 10 CFR 54.4(a)(2) intended function. Other class 5 piping that is connected to class 3 check valves, isolation valves, and piping serving the RMWST has a structural integrity (attached) intended function. The components that have 10 CFR 54.4(a)(3) intended functions are included in the boundary descriptions described above.

- M1-0241-A-LR
- M1-0242-LR
- M1-0242-A-LR
- M1-0242-B-LR

Unit 2:

- M2-0241-LR
- M2-0242-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The RMW subsystem nuclear safety related function is to provide a Seismic Category I source of makeup water for the following systems:

a) CCW System
b) Safety Chilled Water System
c) SFP Cooling and Cleanup System
d) CVCS

(2) In addition, the DRMWS has containment penetrations which support the containment pressure boundary.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provide water supply to fire suppression in containment, which is relied upon to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48).

(2) Accommodates and is compatible with environmental conditions that demonstrate compliance with the Commission's regulations for EQ

(10 CFR 50.49). The DRMWS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

2.3.3.5. Emergency Diesel Generator and Auxiliary Systems

Description

The Emergency Diesel Generator (EDG) and Auxiliary Systems consists of the DG sets and the following auxiliary systems:

- Diesel Generator Fuel-Oil Storage and Transfer System (DGFOSTS)
- Diesel Generator Cooling Water System (DGJWS)
- Diesel Generator Starting System (DGSAS)
- Diesel Generator Lube Oil System (DGLOS)
- Diesel Generator Combustion Air Intake and Exhaust System (DGAIES)

Diesel Generator Sets

Two full capacity DG sets are supplied for each unit. Each DG set automatically starts in emergency mode upon undervoltage on its respective emergency bus or SI actuation signal. Emergency buses are normally fed from offsite power. Upon loss of offsite power (LOOP), automatic bus transfer to the alternate power source occurs. However, if the alternate source is not available, the DG starts. Each DG and its distribution system is designed and installed to provide a reliable source of redundant onsite generated (standby) AC power.

The engine is diesel oil, four-cycle 450 rpm, turbocharged, water-to-water cooled with SSW.

Diesel Generator Fuel-Oil Storage and Transfer System

The DGFOSTS is designed to supply a reliable source of fuel oil for the four emergency DG sets for a period of not less than seven days for continuous operation at rated load.

Four DG sets are supplied by four separate fuel-oil system trains, with each train consisting of a buried storage tank, two transfer pumps, day tank, piping, and I&C necessary for reliable operation. Connections are provided for filling and venting of the storage tanks, and provisions are made for the draining and sampling of fuel oil and removal of condensate. Each day tank is provided with instrumentation to monitor and alarm low and high fuel levels.

Two fuel-oil transfer pumps are located in each DG room. Each pump takes suction from its associated storage tank and discharges to the associated day tank.

Each diesel fuel oil storage tank is equipped with a vent line with a flame arrestor, level transmitter, and a fill line with shut-off valve. The fuel oil storage tanks are located in the yard buried next to the Diesel Generator Building (DGB). The fuel oil storage tanks are designed to Seismic Category I requirements and corrosion protection for these tanks is provided. The tanks are externally coated, and cathodic protection is applied.

A strainer is located downstream of each redundant fuel oil transfer pump. In addition, duplex strainers are located downstream of the fuel oil day tank on the engine skid. These strainers are provided to catch any suspended sediment. A duplex filter is also located on the engine skid upstream of the fuel supply header to collect any additional suspended sediment.

The day tanks supply an immediate source of fuel-oil to the DG sets. Fill, vent, drain connections and a return line to the storage tank for overflow are provided for each tank.

The engine fuel is No. 2 diesel fuel oil as specified by the diesel manufacturer with quality limits as stated in ASTM D975.

Diesel Generator Cooling Water System

The DGJWS is designed to allow the DGs to be rapidly loaded and operate continuously at their maximum ratings. Components within the DGJWS are sized to remove the maximum heat produced using service water as a cooling medium. The DGJWS for each DG consists of two subsystems: a closed cooling water loop (jacket water) for cylinder jackets, cylinder heads, turbochargers, air intercoolers, and lube oil cooler; and an external cooling water supply (service water) which cools the jacket water heat exchanger. The external cooling water supply includes supply and return piping that is part of the auxiliary module.

When the DGs are not in operation, each engine has a thermostatically controlled electric standby heater and motor-driven keep warm pump that are provided to reduce the effects of fast start thermal transients on long-term maintenance requirements.

The DG sets are capable of operating at rated speed for seven (7) days with no load across the terminals and are capable of assuming design sequenced and continuous loading or any part thereof, during this period. The DG sets have no minimum loading requirements.

The DGJWS is designed as a closed system with a vented standpipe at the highpoint. The standpipe, with a low level alarm, ensures sufficient NPSH for the engine driven jacket water pumps.

Jacket water temperature is maintained constant by the use of an automatic three-way valve which is thermostatically operated. Vents at high points in the system ensure that no air is trapped in the system.

Leakage in the DGJWS can result in a loss of coolant inventory. This will cause a high jacket water temperature alarm followed by a possible trip of running the EDG in NORMAL mode. A low level jacket water alarm is also provided.

Long-term corrosion and organic fouling in the DGJWS is minimized by the use of demineralized water mixed with $NaNO_2$.

Diesel Generator Starting System

The DGSAS is an air-powered system designed to start the DG set. Diesel engines are started by injection of compressed air into the cylinders. Each DG has two

100 percent capacity air systems. Each system includes air compressors, air receivers, air dryers, and two solenoid starting valves. Either starting air system satisfies EDG operability.

Each receiver is sized to contain enough air for five starts. Two air supply lines are provided, each having redundant solenoid starting valves. One valve passes enough air to start the diesel engine, thus ensuring a sufficient supply of starting air if one valve fails to operate. Each receiver also has a valve to permit periodic blowdown of accumulated moisture and foreign material.

Instrumentation is provided to monitor the operation of the system. On low receiver pressure, redundant pressure elements actuate an alarm in the DG room and a trouble alarm in the Control Room.

Diesel Generator Lube Oil System

Each DGLOS is designed to provide adequate engine lubrication under all operating conditions, including immediate full-load operation after starting. Each DG operates as a dry sump system and has one main lube oil pump that is engine driven. A positive displacement pump draws oil from the sump through a course strainer. The lube oil travels through the pump, a cooler, a filter, and then through a strainer to the engine. Filtering ensures oil is of acceptable quality. The DGLOS is cooled by the DGJWS. The DGLOS is a closed system. Refilling of the DGLOS is accomplished through a normally capped two-inch connection.

The required oil quality as specified by the engine manufacturer is maintained by automatically filtering and straining the oil as it is circulated in the engine.

The engine crankcase is protected from over pressurization by the following design features. The system is equipped with alarms and trips initiated by high oil temperature and/or low pressure, which shuts down the DG if operating limits as specified by the engine manufacturer are exceeded. The DGLOS trips are blocked during emergency operation. The crankcase is equipped with centrifugal blowers for crankcase ventilation during DG operation. The crankcase is also equipped with blowout panels to protect the unit from damage.

The lubrication oil sump, the lubrication oil filter and the lubrication oil strainer are all vented.

When the engine is not operating, a motor-driven prelube pump automatically starts and draws oil from the sump, passes it through a strainer and a filter, and then into the engine lubricating system. This recirculation of lube oil continues until the engine receives another start signal. The oil is heated by an electrical immersion heater in the sump. This ensures continuous prelubrication of the engine and standby heating of the oil.

The heated oil, in this keep warm mode, is circulated throughout the engine block but does not feed the turbocharger’s lubrication header. Check valves in the lube oil system ensure that oil is kept near these assemblies so that lubrication can be provided by the engine-driven lube oil pump within one-half of one engine revolution on startup.

Diesel Generator Combustion Air Intake and Exhaust System

The DGAIES is designed to provide adequate combustion air for each EDG under all operating conditions and adequate capability to direct the engine exhaust to the outside air under all operating conditions. The DGAIES consists of the air intake system, turbocharger, turbocharger air intercooler, and the exhaust gas system. Each engine has its own independent DGAIES.

The intake system consists of a filter, silencer, flexible connection, adapter for connection to turbocharger intake, air intake duct connection, and interconnection piping. The volume of intake air is sufficient to ensure continued operations under emergency conditions.

The turbocharger consists of an air compressor and a gas turbine coupled on the same shaft.

The turbocharger air intercooler transfers heat produced from the compression of combustion air by the turbocharger to the DGJWS.

The diesel generator combustion exhaust system consists of an outlet adapter for the turbocharger gas turbine outlet, a flexible connection, silencer, exhaust duct connection, interconnecting piping, and a relief valve.

The diesel generator combustion air intake is provided with intake air filters to protect the engine from dirt or other contaminants. The missile protected intake is located 36-ft above ground level to minimize the intake of ground dust or debris. The missile protected inlet protects the diesel generator combustion air intake system from external missiles and prevents the entrance of rain or snow. The combustion air intake and the exhaust are located apart so that dilution or contamination of the intake air by exhaust products does not affect operation of the DGs. The engine exhaust is directed upward and away from the intake, which is directed downward. The intake is located at a sufficient distance from the onsite bulk gas storage to preclude any contamination of the intake air due to an accidental onsite gas release.

The exhaust pipe downstream of the exhaust silencer contains a drain which prevents water from collecting. A full-flow relief valve located upstream from the exhaust silencer permits the engine to continue operating if the portion of the diesel generator combustion exhaust gas system exposed on the roof is crushed by a tornado generated missile. If the normal flow path for the exhaust is blocked, this valve will discharge the exhaust gases directly to the atmosphere. There is no piping downstream of the valve.

Boundary

The EDG and Auxiliary Systems boundaries for LR are reflected on the LRBDs listed below.

The EDG and Auxiliary Systems scoping boundary encompasses the diesel engines and includes the DGFOSTS, DGJWS, DGSAS, DGLOS, and DGAIES.

DGFOSTS scoping boundaries are shown on LRBDs M1-0215-F-LR, M1-0215-G-LR, M2-0215-F-LR, and M2-0215-G-LR. Beginning at the fuel oil storage tank, fuel is drawn by fuel oil transfer pumps and delivered to the fuel oil day tank. Fuel is drawn from the day tank, fed through duplex strainers and filters, and delivered to the engine via the fuel oil pump, fuel injectors, and fuel injector pumps. Unused fuel is returned to the fuel oil day tank via bypass line and drip waste return pump.

DGJWS scoping boundaries are shown on LRBDs M1-0215-H-LR, M1-0215-J-LR, M2-0215-H-LR, and M2-0215-J-LR. The DGJWS includes both open cycle and closed cycle portions. In the open cycle portion, SSW travels from inlet piping to the jacket water cooler. After cooling the closed cycle portion, SSW is returned via outlet piping. The closed cycle portion, starting at the jacket water cooler, is drawn from the jacket water cooler and enters the lube oil cooler where it is used to cool lubricating oil. After exiting the lube oil cooler, jacket water is drawn into intercoolers and turbochargers where it is used to cool the diesel engines and intake air to the diesels. After leaving the engine, jacket water is returned to the DGJWS standpipe. Jacket water from the standpipe is pumped via engine and auxiliary jacket water pumps where it is returned to the jacket water cooler, completing the closed loop. A keep warm pump draws jacket water from the standpipe and circulates it during standby, in order to avoid thermal transients during startup.

DGSAS scoping boundaries are shown on LRBDs M1-0215-D-LR, M1-0215-E-LR, M2-0215-D-LR, and M2-0215-E-LR. The DGSAS starting air compressors and air dryers are NNS and are not within the scope of LR. Scoping boundaries begin at the outlet piping from the air dryers. Air is drawn from this piping into starting air receivers. From the air receivers air is drawn into the engine after passing through strainers and starting air admission valves.

DGLOS scoping boundaries are shown on M1-0215-B-LR, M1-0215-C-LR, M2-0215-B-LR, and M2-0215-C-LR. Beginning at the lube oil sump tank, lubricating oil may be drawn from the lube oil heater via pre-lube pump, through pre-lube filters and strainers, and into the engine. Lubricating oil may also be drawn from the lube oil sump tank by engine and auxiliary lube oil pumps into the lube oil cooler. After being cooled by jacket water within the cooler, lubricating oil passes through duplex filters and strainers and enters the engine, lubricating various engine components. Lubricating oil is also directed into left and right bank turbochargers for lubrication. After lubricating engine components and the turbochargers, lubricating oil is returned to the lube oil sump tank.

DGAIES scoping boundaries are shown on M1-0215-LR, M1-0215-A-LR, M2-0215-LR, M2-0215-A-LR. Intake air is drawn from an outdoor missile protected intake, where it is split and fed through two sets of intake air filters and air inlet silencers. Air is drawn into the engine and through right and left bank intercoolers and turbochargers. Exhaust air exiting the turbochargers is exhausted outdoors through the DGB roof away from the intake, after passing through an exhaust silencer. A crankcase vacuum blower and associated piping are utilized to remove contaminants from the intake air manifold and direct them out through the DGB roof.

Included in the LR scoping boundary of the EDG and Auxiliary Systems are those portions of NNS piping and equipment that extend beyond the nuclear safety related/NNS interface up to the location of the first seismic anchor, or to a point no longer in proximity to equipment performing a nuclear safety related function, whichever extends further. Included in this boundary are components relied upon to preserve the structural support intended function. Included in this boundary are pressure-retaining components relied upon to preserve the leakage boundary intended function of this portion of the system.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide power to nuclear safety related components. The EDG and Auxiliary Systems starts and is available to supply power for nuclear safety related loads upon undervoltage on its respective emergency bus or receipt of SI actuation signal.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The EDG and Auxiliary Systems are fire safe shutdown systems utilized to provide support services.

(2) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63). Components within the EDG and Auxiliary Systems are required to cope with SBO to satisfy the requirements of RG 1.155 and 10 CFR 50.63.

2.3.3.6. Equipment and Floor Drainage Systems

Description

The Equipment and Floor Drainage System is provided to collect liquids from the various systems in the plant, separate them according to purity and radioactivity, and to route them to the proper location for disposal or recycle. It also monitors leakage in vital areas.

Separate drain headers are provided for each drain type according to activity and quality level to prevent mixing of different liquid wastes. Equipment drains are also provided in some areas in addition to floor drains so that non-radioactive and radioactive waste can be drained separately. The Equipment and Floor Drainage System is also provided with radiation monitors to detect radioactive contamination caused by equipment failures or accident conditions before discharging the drains to the environment. The drainage system used to carry clean water is completely separate from the drainage system used to carry potentially radioactively contaminated water to prevent the accidental release of radioactive material to the environment.

Collection and transfer of liquids from the lower levels of buildings are facilitated by sump pumps, sumps, and drain collection tanks. Spare, full-capacity sump pumps are provided at each transfer point in the drainage system. Backwater valves are provided, as necessary, to prevent water from backing up through a drain line and possibly impairing the function of nuclear safety related equipment. Ball Float devices, which allow water to drain from an area but prevent steam propagation or unfiltered air in leakage to other interconnecting areas, are provided as necessary for the protection of essential systems and components due to postulated piping failures per FSAR Section 3.6B and for control room habitability during a DBA. The nuclear safety related portions of the VD that penetrate the containment shall be provided with leak detection, isolation, and containment capabilities having redundancy, reliability, and performance capabilities which reflect the importance to safety of isolating these piping systems.

Boundary

RCB Drains

Leakage from all RCB floors is directed to one of two containment sumps. The reactor cavity is also provided with a sump at the lowest point in the RCB. The pumps from all three sumps are aligned through a common flow totalizer with floor drain tank No. 1 and have a normally closed line into the waste holdup tank. The RCB drains do not function during an accident and are isolated by two fail-closed, air-operated containment isolation valves, one inside and one outside containment.

SGB Drains

Drains from all Safeguards areas above EL. 785-ft 6-in. are routed directly to the floor drain tank, CCW drain tank, or to one of the sumps. Each sump has two nuclear safety related pumps to prevent flooding from continuous system leakage and to detect a passive failure. The area at or below EL. 785-ft 6-in is provided with a sump, independent from the sump serving the other area with the drain headers discharging into the closed SGB sumps.

The Diesel Generator Room sump pumps are normally aligned for discharge into the Wastewater Management System, for treatment prior to discharge. In-scope components are addressed up to the flange connection as shown on M1-0237-LR.

CCW tank room sump No. 3 collects drainage from the CCW drain tank, containment spray and RHR pumps, and is aligned to discharge into the Wastewater Management System. CCW tank room sump No. 3 is only fed by drains which collect fluid from normally non-radioactive sources. In-scope components are addressed up to the flange connection as shown on M1-0237-LR.

SGB drain sumps 1 and 2 (for each unit) are normally aligned for discharge into the waste holdup tank. The Auxiliary to SGB Seismic Gap is equipped with automatic level controls for a small effluent pump. The drains from the floor drain tank and floor drain tank room utilize a locked closed valve to prevent recirculation of the tank contents back into sump No. 1 in the event of failure of the tank or piping within the tank cubicle.

AB Drains

The AB drainage is routed via several different flow paths. The drainage of the southern half of the AB above EL. 792-ft is accomplished by a gravity drainage system into the floor drain tank for Unit 1. At or below EL. 792-ft, leakage from the southern half of the AB is collected in various sumps. Drainage from the Battery Room, Secondary Sampling Room, Chemical Storage Room, Air Compressor Room, Mechanical Equipment Room, and the Unit 2 Cable Spreading Room is routed to Sump No. 11. The sump pumps are normally aligned to discharge to the Wastewater Management System. Sump Nos. 3 and 10 receive drainage from the CCW heat exchangers and nuclear safety related chillers, respectively. Sump No. 3 additionally receives drainage from the discharge of service water tunnel sump pumps Nos. 1 and 2. Sump No. 10 pumps are normally aligned to discharge to the Unit 1 CCW drain tank, with a normally closed connection to the Unit 2 CCW drain tank. Sump No. 3 pumps are normally aligned to discharge to the Waste Management System low volume waste (LVW) pond. The pumps have normally closed discharges to the Units 1 & 2 CCW drain tanks. Sump Nos. 4, 5 and 9 receive drainage from the remainder of the southern half of the AB below EL. 792-ft. The sump pumps are aligned to discharge to floor drain tank No. 1. The northern half of the AB above EL. 810-ft 6-in is drained by means of a gravity drainage system that ties into the drainage system and the drainage for the southern half of the AB routed to floor drain tank No. 1. The portions of the northern half of the AB at EL. 790-ft 6-in are drained into sumps. Sump Nos. 6 and 8 take drainage from the waste evaporator condensate tank and recycle evaporator feed pump areas, respectively. In addition, sump No. 8 takes drains from a portion of Unit 2 TB EL. 810-ft 6-in. The sump pumps are aligned to discharge into the waste holdup tanks. Sump No. 2 collects the remainder of the drainage from the lowest part of the northern half of the AB. The sump pumps are aligned to discharge to floor drain tank No. 1.

The discharges from sumps 1, 7 and 12 are directed to floor drain tank 1 with an alternate closed line to floor drain tank 3.

TB Drains

All drainage piping and equipment in the TB are NNS and are not required to function after an accident or for safe reactor shutdown. Therefore, the components within the Equipment and Floor Drainage System located in the TB are not included in scope.

FB Drains

All drainage from the FB, with the exception of the Service Water Tunnel, is directed into one of two sumps. Most drainage from the FB is directed to FB sump No. 1, which is located at EL. 800-ft 2-in. FB sumps 1 and 2 are aligned to discharge to floor drain tank No. 1, which is located in the SGB at EL. 773-ft.

Drainage from the FB service water tunnel is directed into two sumps. Service water tunnel sumps 1 and 2, which are located at EL. 785-ft 6 in, are aligned to discharge to the ABFD sump 3.

The evaluation boundaries for the Equipment and Floor Drainage System are shown on the following LRBDs:

Unit 1:

- M1-0236-LR
- M1-0236-A-LR
- M1-0236-B-LR
- M1-0236-01-LR
- M1-0236-01A-LR
- M1-0236-02-LR
- M1-0236-02A-LR
- M1-0236-03-LR
- M1-0236-04-LR
- M1-0237-LR
- M1-0237-01-LR
- M1-0238-LR
- M1-0238-A-LR

Unit 2:

- M2-0236-LR
- M2-0236-A-LR
- M2-0236-B-LR
- M2-0236-03-LR
- M2-0238-LR
- M2-0238-A-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The Equipment and Floor Drainage System includes piping that penetrates the primary containment. The containment penetrations include containment isolation valves to assure that radioactive material is not inadvertently transferred out of containment. Therefore, the Equipment and Floor Drainage System provides containment pressure boundary.

(2) Prevent flooding of safety related equipment. Safeguard building floor drain sump pumps prevent flooding of the safeguards building via pumping water from the sumps to the WPS floor drain tanks.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function. The Equipment and Floor Drainage System includes water filled components in the Unit 1 and Unit 2 SGBs, AB, RCB, and FB that have the potential for spatial interaction with nuclear safety related components.

(2) The Equipment and Floor Drainage System provides functional support to preclude flooding due to continuous system leakage in rooms that contain nuclear safety related equipment.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) The Equipment and Floor Drainage System provides drainage in areas protected by fixed water fire suppression systems (10 CFR 50.48). The VD and FDS provides adequate drainage to protect nuclear safety related equipment during internal flooding caused by an FPS discharge.

(2) The Equipment and Floor Drainage System is relied upon in the safety analyses and plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The equipment and floor drainage system includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

2.3.3.7. Fire Protection System

Description

The FPS is a standby, mechanical system designed to detect, alarm, and extinguish fires. The FPS is divided into two basic subsystems: The Fire Detection System and the Fire Suppression System. The Fire Detection System is a plant-wide instrumentation system provided to detect fires in various areas of the plant and to alert the Control Room operators of a fire and its location. The fire suppression system includes such firefighting equipment as sprinkler systems (wet pipe, deluge, and pre-action), water spray, standpipe and hose stations, halon systems, and portable extinguishers.

Water is supplied for the standpipes and suppression systems from two dedicated above ground storage tanks, that are maintained at a specific level by a treated water supply, via an underground piping distribution system and water supply lines for each building. The main loop is divided into sections by post indicator valves to allow isolation of the loop in case of a line break. There are three 50 percent capacity fire pumps to supply water to the system. One is an electric motor driven pump, and the other two pumps are diesel engine driven. Water is supplied to the underground fire loop by the lead pump, the electric motor-driven pump, when the jockey pump cannot maintain the system pressure above a predetermined set point. An emergency fill line is provided from the SWIS to refill the tanks with water from the SSI via use of an electric motor driven pump. The electric motor driven pump is provided to allow either tank to be refilled within 8 hours after using its contents to extinguish a fire.

The SGB, FB, and AB have internal loops to supply suppression and standpipes systems. These loops have multiple connections to the underground loop. Valves are available for isolation of sections of the loops as well as isolation of the internal loop from the underground loop. Each suppression and standpipe system has a shutoff valve to facilitate work on the system.

The TBs have an internal loop to supply standpipes. This internal loop has multiple connections to the underground loop in Unit 1 and Unit 2. Crosstie lines are provided between Unit 1 and Unit 2 TBs to facilitate isolation of sections of either loop.

The suppression systems for the DG day tanks are supplied from the main loop independent of each other. Each system has a deluge valve, a cutoff valve, and a detection system. The systems are actuated automatically based on detection of a fire or manually adjacent to the respective area.

The fire pump house structure is protected by an automatic wet-pipe sprinkler system. Water flow and valve tamper alarms are provided at the pump house location and in the Control Room. The deluge water spray systems for the ventilation units (atmosphere cleanup units), except the containment preaccess units, are supplied by the interior building supply loop. The preaccess units are supplied by the demineralized water system.

The halon system for each cable spreading room consists of a detection system, storage cylinders, manifold and header assembly, control valves, piping, nozzles, and local control panel. Each system is designed with two charges of halon. Halon is released automatically after receipt of a fire signal from detectors located in the cable spreading room. The Unit computer rooms are each provided with a manually actuated halon system, and ionization smoke detection provides control room personnel notification of a fire.

Fire hose stations in the FB are required to provide emergency makeup to the SFPs to maintain levels and ensure cooling of stored spent fuel.

Boundary

The FPS scoping boundary includes the two atmospheric fire water storage tanks (FWSTs) which are located outdoors on the east side of the FB as shown on MX-0225-07-LR. PW provides make-up water to these tanks. The FPS boundary starts from valves XFP-0360 and XFP-0363. The suction lines extend from each tank to the fire pump suction header in the fire pump house which houses the three fire pumps, jockey pump and their associated drivers, each installed in separate rooms. An emergency make-up FP line to the FWSTs is provided from the SWIS as the Emergency fill source, drawing water from the SSI.

The components of the diesel engine for the fire pumps are shown on MX-0225-09-LR. The diesel engines for fire pumps and the engine mounted components are part of the active engine assembly. These active components are not subject to AMR. The exhaust piping, exhaust silencer, flame arrestor and heat exchanger are subject to AMR.

There is a single vertical centrifugal fire pump and associated piping located in the SWIS that provides emergency makeup water to either FWST shown on M1-0225-LR. Also located in the SWIS is a diesel driven fire pump (DDFP) that is enclosed in a separate room and has been abandoned in place. The DDFP and associated piping do not interface with other components found within the SWIS and therefore are not within the scope of LR. Similarly, a jockey pump is also abandoned in place and is isolated with a blind flange and therefore not in scope.

Water from the FWSTs is supplied to various site suppression systems utilizing an underground piping distribution system as shown on M1-0225-06-LR. Suppression systems to structures that fall under site facilities, which are not in-scope structures, are not included in scope.

Connections to the 12-in underground loop supply water to the supply headers in the Unit 1 and 2 SGBs and the AB. The FPS for each building is supplied by multiple fire water supply lines.

The TBs have an internal loop to supply standpipes. This internal loop has multiple connections to the underground loop in Unit 1 and Unit 2. The TB consists of one fire area which extends from EL. 775-ft 4-in to the roof of the TB. This fire area includes both the Unit 1 side and the Unit 2 side of the TB. The Fire Suppression System for the TB is shown on M1/2-0225-01-LR.

The main supply headers for suppression systems in nuclear safety related areas of the plant run through the north-south corridors of the Unit 1 and Unit 2 SGBs and the AB on the 790-ft 6-in, 810-ft 6-in, 831-ft 6-in and 852-ft 6-in elevations as shown on M1-0225-02/02A-LR, M1/M2-0225-03/03A-LR, and M1-0225-04-LR.

The Fire Suppression System for containment, Units 1 and 2, are shown on M1/2-0225-05-LR.

The DRMWSs which provides the primary supply of water for the preaccess filtration units spray systems interfaces with the FPS at Valve 1/2FP-0590. Similarly, the Plant Gas for Nitrogen supply interfaces with the FPS at valve location 1/2FP-0607.

The Halon System is used as a fire suppression system in the Unit 1 and 2 cable spreading room. The individual halon systems consist of main and reserve banks of cylinder(s), with an equal quantity of agent in both banks, which are manifolded to the distribution piping. The main and reserve Unit 1 and Unit 2 Cable Spreading Room systems each consist of three banks of four cylinders which discharge simultaneously upon actuation. The Halon System is shown on M2-0225-011-LR.

The RCS oil Spillage Protection System, depicted on M1-0252-01-LR and M2-0252-01-LR, collects RCP bearing lubricating oil leakage. This system responds to 10 CFR Part 50 Appendix R item O and therefore is included with the FPS.

The FPS boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0225-LR
- M1-0225-01-LR
- M1-0225-02-LR
- M1-0225-02A-LR

- M1-0225-03-LR
- M1-0225-03A-LR
- M1-0225-04-LR
- M1-0225-04A-LR
- M1-0225-05-LR
- M1-0225-06-LR
- M1-0252-01-LR

Unit 2:

- M2-0225-01-LR
- M2-0225-03-LR
- M2-0225-03A-LR
- M2-0225-05-LR
- M2-0225-11-LR
- M2-0252-01-LR

Common:

- MX-0225-07-LR
- MX-0225-08-LR
- MX-0225-09-LR

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide primary containment pressure boundary.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Ensure adequate cooling in the SFP to maintain stored fuel within acceptable temperature limits.

(2) Provide backup cooling. The FPS may be aligned to the jacket water heat exchangers for EDGs, as well as the lube oil coolers for SI pumps and CCPs, in the event of a loss of all SSW.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48).

(2) Perform a function that demonstrates compliance with the Commission’s regulations for EQ (10 CFR 50.49). The FPS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

Spray nozzle (charcoal filters, deluge, halon)	Spray
Sprinkler head	Pressure boundary Spray
Strainer	Filter Pressure boundary
Tank (atmospheric fire water storage tanks) (diesel driven fire pump fuel oil tanks) (RCS oil spillage tanks) (retard chamber)	Pressure boundary
Tubing	Pressure boundary
Valve body	Pressure boundary

2.3.3.8. Plant Ventilation Systems

Description

The Plant Ventilation Systems, including select subsystems, maintain ambient temperature and conditions in various areas of the plant and are described, separately, below.

Containment Ventilation Systems

Separate ventilation systems are furnished for the Containments of Units 1 and 2. The Containment Ventilation Systems consist of the Containment Recirculation and Cooling, CRDM Ventilation, Neutron Detector Well Cooling, Reactor Coolant Pipe Penetration Cooling, Preaccess Filtration, Containment Pressure Relief, and Containment Purging Systems.

Containment Recirculation and Cooling System

The environment within containment is controlled by the Containment Recirculation and Cooling System during startup, power operation and hot standby. During normal operation, air in the Containment is recirculated and maintained at or below 120°F. Four cooling units are provided, each sized for 33 1/3 percent (65,000 scfm) of the normal duty cooling load. Standby units are manually actuated on receipt of a failure alarm in the Control Room. Fans are provided with a connection to the Class 1E buses to preclude loss of cooling caused by LOOP. The cooling medium is water provided from the plant ventilation chilled water supply during normal operation and LOOP, because the plant ventilation chillers are also supplied from the Class 1E buses during LOOP conditions. Instruments are provided to continuously monitor air temperature, humidity, and pressure within the Containment during all phases of reactor operation. The Containment recirculation units together with the CRDM Ventilation System remove the entire Containment heat load during normal operation and LOOP conditions including the CRDM heat load. The neutron detector well heat load is removed by a separate set of coils. The cooled air is distributed throughout the Containment by the supply ductwork with no return ductwork provided. Instead, the warm air rises through various openings in the floors and returns to the suction side of the fan coil units.

CRDM Ventilation System

The CRDM Ventilation System maintains temperatures within the CRDM shrouds. The CRDM cooling coils supplement the general containment cooling provided by the Containment Recirculation and Cooling System. Containment air is drawn through the CRDM shrouds and through the CRDM cooling coils and discharged to the containment atmosphere. Two 100-percent capacity fans are provided. The standby unit, isolated by dampers in the duct, is manually actuated on receipt of a failure alarm in the Control Room. In the event normal power supplies are interrupted and the reactor is maintained at hot standby, the CRDM fans are operated from the emergency power supply. The cooling medium to the CRDM cooling coils is provided by the plant ventilation Chilled Water System. The CRDM Ventilation System does not operate in the event of a DBA.

Neutron Detector Well Cooling System

Neutron detector well cooling units prevent neutron detectors from exceeding their temperature limitations. These units also provide cooling for reactor shield wall concrete and nozzle supports. The neutron detector well and nozzle support cooling system is a closed loop system. The air is cooled and directed up around the reactor from the underside of the vessel. Part of the air cools the neutron detectors, and part of the air is directed to the nozzle supports. The air is returned to the fan via piping embedded in the concrete. Two 100-percent capacity cooling units are provided with each consisting of a fan, two cooling coils, and inlet and outlet dampers. Both units are connected to redundant EDG buses to preclude loss of cooling in case of a LOOP. A temperature monitoring device continuously monitors air temperature in the return air ducts of the detector well system.

Containment Preaccess Filtration

The need for safe, periodic, or emergency access to the Containment necessitates the use of Containment preaccess filtration. This filtration system provides air circulation and filtering throughout all Containment areas. Containment preaccess filtration equipment reduces the concentration of fission product particulate activity in the containment atmosphere prior to personnel entering the Containment. Air inside the Containment is recirculated by two 50-percent capacity filtration units. Each filtration unit includes a fan, a roughing filter, two HEPA filters, and one iodine adsorber. Both units are required to operate for the design iodine removal capacity. The equipment is designed to remove fission product iodine gas as well as radioactive particles to permit prompt access to the Containment. Ductwork connected to the suction side of the preaccess filtration unit extends to all levels of the Containment to ensure that the containment atmosphere is uniformly decontaminated. Air is discharged at the suction side of the Containment recirculation system, which supplies the air through ductwork and guarantees proper mixing. Charcoal adsorbers are provided with a fire protection water deluge system.

Containment Purge Supply and Exhaust System

Containment purge supply and exhaust equipment satisfies the prerequisites for safe, prolonged access to the Containment following shutdowns. The system is utilized during shutdown only; it is not used during startup, power, or hot standby operations.

Fresh, outside air is passed through a filter and heating and cooling coils and discharged near the recirculation supply fans in the Containment. Thermostatically controlled electric heating coils are provided in the purge supply duct to maintain minimum temperatures for personnel comfort during shutdown. One 30,000 scfm filter heating and cooling coil plenum and a fan are required. The containment purge supply isolation valves are designed to close automatically on detection of high radiation levels by the containment air radiation monitor or on a Phase A isolation signal.

Exhaust air is drawn through a prefilter, two HEPA filters, and an iodine adsorber and exhaust fan, and released to the atmosphere via the plant ventilation vent. Two filter plenums with associated fans are required to maintain design purge rate. The air is monitored before discharge to the environment, to limit the concentration of contaminants. The containment purge exhaust isolation valves are designed to close automatically on detection of high radiation levels by the Containment air radiation monitor or on a phase A isolation signal.

Containment Pressure Relief System

The Containment Pressure Relief System is designed to relieve excess Containment pressures caused by temperature transients or air leakage from pneumatic actuators during normal operation. The Containment Pressure Relief System is connected to the Containment purge exhaust duct outside Containment, downstream of both system Containment isolation valves and upstream from the primary plant exhaust filters. This connection ensures that any air from the Containment is filtered prior to release to the atmosphere, via the plant ventilation vent. The Containment Pressure Relief System is designed to reduce the Containment pressure from a maximum of 1.5 psig to atmospheric pressure.

The pressure relief line is connected to the Containment purge exhaust system; the Containment Pressure Relief System requires only one penetration. The exhaust air is decontaminated by the primary plant modular filtering trains prior to being discharged to the plant ventilation discharge duct. Both pressure relief Containment isolation valves automatically close if high radiation is detected by the containment particulate-iodine-gaseous monitor, on a phase A isolation signal, or on containment ventilation isolation. The isolation valves are 18 in. in diameter and will close within three seconds after receiving the signal. The valve and actuator design bases include consideration or buildup of Containment pressure for the LOCA break spectrum and relief line flows as a function of time up to and during valve closure. A debris screen is provided inboard of the inside containment isolation valve. The screen is designed to Seismic Category II criteria and is placed in the flow path of the Containment Pressure Relief System for protection of the isolation valves from debris.

Reactor Coolant Pipe Penetration Cooling System

The Reactor Coolant Pipe Penetration Cooling System supplies high velocity cooled air to each of the reactor coolant hot and cold leg pipe penetration supports. This cool air flow removes heat conducted to the supports by the pipe to keep the pipe tunnel concrete temperature below 200°F. The system consists of four fans (2000 scfm each), fan outlet isolation dampers, and ductwork. The fans are the centrifugal, direct drive type, and parallel blade, counterweight operated gravity dampers at each outlet to prevent free wheeling of the standby fan. The Containment Recirculation System supplies tempered air to the immediate area surrounding the fan inlets. Air is drawn in by the operating fan and supplied through ductwork directly to each pipe penetration. The warm air is forced out by the supply air and rises up, thus being cooled, and recirculated by the Containment Recirculation System. The ductwork is arranged with balancing dampers to ensure that equal amounts of air are supplied to the four supports it connects. The Reactor Coolant Pipe Penetration Cooling System is not required to operate following a LOOP or a DBA.

Control Room Area Ventilation System

The Control Room habitability systems are designed to ensure that the Control Room is habitable for a period not less than 30 days following any LOCA. The Control Room air-conditioning system has a recirculation mode designed to maintain Control Room ambient conditions suitable for personnel occupancy during accident conditions. A set of emergency filtration units removes airborne activity from outside air during emergency pressurization and filtration modes of operation.

The Control Room design provides for a single Control Room serving both units. The Control Room HVAC System is designed to serve this area as well as the computer rooms and offices located at the same elevation and at elevation 840 ft 6 in. The Control Room HVAC system is designed to remove all heat generated by the equipment, computers, lighting, personnel, and so forth and to provide a safe operating condition for personnel. Two modular air-conditioning units provide the cool air required, with two units of the same size on standby to address the single failure criterion. Each modular air-conditioning unit contains a roughing filter, cooling coil, heating element, humidity control equipment, fan, and associated instrumentation controls

The cooling coils are the direct-expansion, refrigerant type and suitable for refrigerant R-12. The coils of each modular air-conditioning unit are connected to separate and independent compressors and water-cooled condensers. Two redundant emergency filtration units are provided for use following DBAs. Each unit comprises a roughing filter, two high-efficiency particulate absorption (HEPA) filters, and iodine adsorbers and booster fans.

The Control Room is pressurized with respect to the environment to prevent infiltration of unfiltered and unmonitored air and to account for leakages. The overpressure is considered sufficient to prevent infiltration because the Control Room building structure is completely airtight, with few penetrations, and designed to withstand tornado generated missiles. This overpressure is maintained by modulating exhaust dampers during normal operation and emergency ventilation.

Overpressure during the emergency recirculation mode is accomplished by introducing up to 800 ft^3/min of filtered air into the Control Room. This air is supplied through a 100-percent-redundant air-cleanup unit consisting of a fan, a mist eliminator, a heater, a roughing filter, two HEPA filters, and an iodine adsorber.

The Control Room pressurized envelope includes the Control Room and all areas adjacent to the Control Room on EL. 831-ft 6-in of the Electrical and Control Building (ECB) containing plant information and equipment that may be needed during an emergency including kitchen, sanitary facilities, and computer rooms. Control Room design is based upon the safe occupation of the Control Room envelope (CRE) during normal operation and for a period of not less than 30 days after a LOCA.

Miscellaneous Ventilation Systems

DGB Ventilation System

Each DG compartment is furnished with a ventilation system sufficient to remove heat from the area. The system consists of a set of intake and exhaust louvers and exhaust fans and is Seismic Category I and ANS Safety Class 3. No redundancy is provided because the diesels are already redundant. The Diesel Generator Room Ventilation Sub-System (DGRVS) consists of two independent trains, one train for each Diesel Generator Area (DGA) (Train A and Train B). Each train consists of four 25 percent capacity vane axial exhaust fans, dampers, louvers, ductwork, and instrumentation necessary for the operation and control of the system.

The Day Tank Rooms Ventilation Sub-System (DTRVS) consists of two independent trains, one train for each DGA. Each train consists of one 100 percent capacity centrifugal exhaust fan, dampers, louvers, ductwork, and instrumentation necessary for the operation and control of the system.

Two (2) electric unit heaters are provided for each DGA (Train A and Train B). I&C are provided for each electric unit heater. The unit heaters are non-safety and are not required to operate during emergency conditions but are required to meet the Seismic Category II requirements, so that in the event of an earthquake the functionality of any Seismic Category I system or component is not adversely affected.

The Diesel Generator Compartment Ventilation System air exhausts are located in the roof of the respective compartments, and intake louvers are on the south and north walls of Unit 1 and Unit 2, respectively. The ventilation systems are Seismic Category I and designed to withstand tornado loads and tornado-related missiles.

Main Steam and Feedwater Piping Area Ventilation System

The MS and Feedwater Piping Area Ventilation System is designed to provide adequate ventilation, to provide sufficient heat in order to ensure freeze protection of equipment during the winter months, and to remove the heat dissipated by the MS and feedwater piping and any additional loads such as lighting or motor operators located in this area. This system is designed to maintain the ambient temperatures of the MS and feedwater areas at between 40°F and 104°F during all normal modes of plant operation. This system is not required to function following a DBA or following a loss-of-offsite power.

Safety related equipment, located adjacent to the MS and feedwater piping area are protected against the effects of MS and feedwater pipe breaks by the use of isolation dampers located where the supply and exhaust ducts penetrate the MS and feedwater piping area. These isolation dampers are Safety Class 3 and Seismic Category I.

The MS and Feedwater Piping Area Ventilation Supply System consists of two 50-percent-capacity vane axial fans connected in parallel and located downstream of a supply housing. The supply housing consists of a roll-type roughing filter, cooling coil, and electric heating coil. The supply air is provided from the Electrical Area Ventilation System as described below.

Electrical Area (Safeguards) Ventilation System

The Electrical Area (Safeguards) Ventilation System is designed to provide adequate ventilation in order to provide sufficient heat to ensure freeze protection of equipment during the winter months and to remove the heat dissipated by the electrical switchgear and associated electrical equipment (including lighting) contained within this area.

The system is designed to maintain the ambient temperature between 40°F and 104°F during all normal modes of plant operation. This system is not required to function following a DBA. The Operator verifies the normal ventilation fans automatically trip following a SI signal and manually trips the fans if required. In addition, emergency fan coil units are provided to maintain the safeguards switchgear train A and train B areas below the maximum ambient temperature of 122°F in the event of loss-of-offsite power or a LOCA, although the temperature may rise up to 129°F for a short period of time during a LOCA. The ductwork associated with the emergency fan coil units is interconnected with electrical area ventilation system ductwork. This ductwork, as well as the emergency fan coil unit, is classified Safety Class 3 in accordance with ANSI N18.2 and Seismic Category I. The coils on the fan coil units are supplied by the safety Chilled Water System.

ECB Uncontrolled Access Area Heating, Ventilation, and Air-Conditioning System

The uncontrolled access area HVAC system is designed to provide adequate ventilation, to provide sufficient heat in order to ensure freeze protection of equipment during the winter months and to remove the heat dissipated by equipment located in cable spreading rooms, battery rooms, and miscellaneous areas. The system maintains the ambient temperature between 40°F min. and 104°F max. during all normal modes of plant operation. It provides sufficient ventilation to the battery rooms to ensure a minimum number of air changes per hour in order to keep the hydrogen concentration of the rooms below the lower flammability limit, i.e., a hydrogen air mixture of 2.0 percent by volume. The battery room exhaust units and associated ductwork are designated ANS Safety Class 3 and Seismic Category I and operate in the event of a DBA. Individual room heaters are supplied to maintain the battery rooms at 70°F min.

The supply system consists of two 50-percent-capacity vane axial fans connected in parallel and located downstream of a supply unit. The supply unit consists of a sheet metal housing which contains a roll filter, an electric heater, and a cooling coil which is supplied water from the non-nuclear-safety related plant ventilation Chilled Water System. Outside air is drawn through louvered openings and an isolation damper, and passes through the supply unit, vane axial fans, and gravity dampers. The supply air is distributed throughout the Control Building and uncontrolled access areas, which contains cable spreading areas, battery and charger rooms, air compressor areas, and portions of a heating and ventilation equipment room.

The exhaust and recirculation system either returns air to the suction side of the supply unit or exhausts the air directly to atmosphere. This is accomplished through a system of exhaust ductwork located throughout the Control Building and uncontrolled access areas. The exhaust and recirculation system consists of two 50-percent-capacity vane axial fans and gravity dampers, both of which are required to direct the return airflow back to the supply unit or to the atmosphere.

A separate ventilation exhaust system is provided for each of the battery and charger rooms. Each battery room ventilation exhaust system consists of two 100-percent-capacity centrifugal fans, and each battery charger room ventilation exhaust system consists of two 100-percent-capacity axial fans; all the fans have pneumatically actuated isolation dampers located on the suction side of the fans and associated ductwork. Supply air is drawn into the battery and charger rooms from adjacent corridors by one of the two exhaust fans. The exhaust fans are arranged in parallel. The battery and charger room exhaust is discharged directly to the environs through a missile-protected roof exhaust vent.

If the supply air handling unit fails to deliver air due to loss of power or any other reason, make up air for the battery rooms is provided by dampers that open the HVAC equipment room to the atmosphere. The suction created by the battery room exhaust fans draws outside air via the HVAC equipment room and supply ductwork into the battery rooms.

Office and Service Area HVAC System

The Office and Service Area HVAC System is designed to provide a comfortable environment for operating personnel by maintaining the temperature for laboratories or other areas that contain calibration or test equipment. The Office and Service Area HVAC System also prevents odors in the toilets, and locker rooms from diffusing to other occupied areas. Potentially radioactive rooms are exhausted through the plant atmospheric cleanup trains prior to releasing the effluents to the atmosphere. This system is designed to function during all normal modes of plant operation, but it is not required to operate in the event of a DBA or following a loss-of-offsite power. Running of the system affects the performance of the PPVS which exhausts air from a portion of areas served by this system. Redundant and diverse, single active failure proof trips of the Office and Service Area Fans are provided to ensure adequate ESF filtration.

The Office and Service Area HVAC Supply System consists of two 50-percent capacity air-handling units each supplying air through a duct distribution system to all the rooms of the office and service area. The air handling units are located in a heating and ventilation equipment room within the control building and consist of a gravity damper, electric heating coil, chilled water cooling coil, and centrifugal fan. Makeup air enters the system through a missile protected inlet. This makeup air is mixed with the return flow from the office and service area rooms and passes through roughing filter. The tempered air is then supplied to the rooms which constitute the office and service area.

Uninterruptible Power Supply (UPS) and Distribution Rooms Air Conditioning System

The UPS and Distribution Rooms Air Conditioning (A/C) System equipment is located at EL. 778-ft of the ECB. The Fan Coil Units are located at EL. 792-ft of the ECB. The system's primary function is to provide cooling for Class 1E electrical equipment in the UPS and Distribution Rooms, Trains A & B, Units 1 and 2, (EL. 792-ft) and the mechanical equipment room (EL. 778-ft). The Fan Coil Units are designed to operate during all modes of plant operation. The air-conditioners are normally on stand-by. However, if a fan coil unit is unavailable, either one of the UPS air-conditioners (Train A or Train B), should be operating.

The Fan Coil Unit portion of the Air Conditioning System is comprised of one 100 percent capacity self-contained Fan Coil Unit. Each unit cools its respective UPS Room. The Heat Sink for the cooling coil is the Safety Chilled Water (SCW) System.

The other portion of the A/C system is comprised of two 100-percent capacity self-contained air-conditioning units located in adjacent rooms that are physically separated by a dividing fire wall. The redundant A/C units are powered from independent Class 1E buses. The UPS and Distribution Room A/C System is ANS Safety Class 3 and Seismic Category I. Each A/C unit consists of replaceable-type filters, refrigerant type (R-12) cooling coil, fan, compressor, condenser, and all necessary I&C. The heat sink on the condenser side of the units is supplied by the CCW System.

SWIS Ventilation System

The heating and ventilation system is designed to maintain the ambient temperatures within the SWIS. The service water pump area exhaust system consists of eight 50-percent-capacity, propeller-type fans, which are mounted on a missile-protected exhaust plenum located in the overhead of the draft damper. The fans are started automatically by locally mounted temperature switches or manually by the intake structure operator. A high temperature alarm in the Control Room is provided.

Outside air is drawn through grated openings with outside air intake screens in the floor of the intake structure located near the base of the pump motors. This air picks up heat dissipated by the service water pump motors. Then the stratified air is discharged by exhaust fans to the outdoors through a missile-protected opening in the side of the intake structure.

Plant Ventilation Systems

FB / SFP Area Ventilation System

The Fuel Building ventilation system is designed to maintain suitable ambient conditions for personnel and equipment during normal plant operations and scheduled shutdowns. During emergency conditions (LOCA with a LOOP) the ambient temperature in the SFP heat exchanger and pump rooms shall be maintained below 122°F, though the temperature may rise to 129°F for a short duration. In addition, a slight negative pressure is maintained during normal operation and during a fuel handling accident to prevent the outflow of unfiltered, contaminated air to the environment. Operating the primary plant ventilation exhaust filter trains minimizes the release of radioactive particulate effluents and radioiodine to the environment.

The primary plant air supply system delivers filtered and tempered outside air to each floor of the FB through a duct distribution system. Each air supply unit consists of a roughing filter, heating, and cooling coils, and a 100-percent-capacity fan.

Emergency fan coil units are provided for the SFP pump rooms. The fan coil units maintain suitable operating temperatures in the pump rooms during all modes of operation. The cooling medium for these fan coil units is the nuclear safety Chilled Water System.

Primary Plant Ventilation System/ AB and Radwaste Area Ventilation System

AB (controlled access area) and radwaste area ventilation system is designed to maintain suitable and safe ambient conditions for operating equipment and personnel during normal plant operation. The primary plant air supply system delivers filtered and tempered outside air to each floor of the AB through a duct distribution system. A minimum of three air supply units of the Primary Plant Ventilation System are normally used for ventilation of the controlled access areas of the Auxiliary, Fuel and Safeguards Buildings.

Each air supply unit consists of a roughing filter, electric heating and cooling coil, and a fan. Chilled water is supplied to the supply air handling units by the plant ventilation Chilled Water System. The AB ventilation system is designed to maintain a slightly negative pressure with respect to the environs during normal operation and during and after a LOCA. The exhaust system ductwork branches to all areas within the AB. Exhaust air is discharged to the atmosphere through the plant ventilation discharge duct after filtration through the modular exhaust filtration units. The AB ventilation duct is monitored by an in-line radiation monitor at the outlet of the ventilation duct header. Each modular non-ESF exhaust filtration unit consists of a roughing and two HEPA filters, an iodine adsorber, and a fan.

Fan coil units are provided for the charging and CCW pump rooms in the AB. The fan coil units maintain pump room temperature at a suitable level during all modes of pump operation. All emergency fan coil units are Seismic Category I and ANS Safety Class 3 and use chilled water supplied by the nuclear safety Chilled Water System as a cooling medium. The positive displacement charging pump fan coil unit is non-safety related and is supplied cooling water from the plant ventilation Chilled Water System.

The FB, AB, Safeguards buildings, and Containment purge supply and exhaust units are all part of a modular ventilation system. This system consists of twelve identical non-ESF exhaust ventilation units, four ESF exhaust units, and eight air supply units. Each of the non-ESF exhaust ventilation units consist of (in order) a roughing filter, HEPA filter, iodine adsorber, HEPA filter, and fan. Each of the eight air supply units consists of a roll filter, heating and cooling coils, and a fan. The total capacity provided is more than required for normal operation; thus, adequate redundancy is provided to prevent a single supply or exhaust fan failure from affecting system operation.

During a LOOP, the non-ESF exhaust fans trip automatically causing the interlocked supply fans to also trip. The operator manually trips any remaining operating supply fans and energizes one (or two) non-ESF exhaust fans to ensure monitoring of effluents.

During a LOCA, in either Unit 1 or Unit 2, all supply and exhaust fans trip automatically on the SI signal while the ESF exhaust fans start automatically. This trip is redundant and meets the single active failure criteria. This will ensure the Primary Plant Ventilation System maintains a slight negative pressure in the negative pressure envelope during all modes of operation.

Chilled water for the cooling coils is provided by the plant ventilation Chilled Water System. Heating coils are electric. The exhaust system is Seismic Category I up to the fan discharge. The air supply system is non-nuclear safety Seismic Category II except for the fan discharge gravity dampers that shall be safety Class 3 and Seismic Category I.

SGB Ventilation System / ESF Ventilation System

The SGB ventilation system is designed to maintain suitable and safe ambient conditions for operating equipment and personnel during normal plant operation and maintains portions of the building under a slightly negative pressure with respect to the environment during all modes of operation. In addition, the operation of the ESF exhaust filtration unit maintains a slightly negative pressure in portions of the building with respect to the environment following a LOCA and loss of offsite power, thus reducing the radioactive effluent released to the environment.

The primary plant air supply system delivers filtered and tempered outside air to each floor of the safety feature area through a duct distribution system. Each supply unit consists of a roughing filter, heating and cooling coils, and fan. Chilled water is supplied to the cooling coils from the plant ventilation Chilled Water System.

Each of the four ESF exhaust filtration units consists of a demister, heater, HEPA filter, iodine adsorber, HEPA filter and fan, and complies with the environmental and components design criteria.

The supply and exhaust system ductwork branches to all areas within the safety feature area. Wherever possible, airflow is directed from areas of lower potential radioactivity to areas of higher potential radioactivity. Unit heaters are provided in specific areas for operator comfort and to maintain ambient temperature above the lower limits for some process piping. Emergency fan coil units, each of which comprises a water cooling coil and fan section, are provided for all compartments which contain motor driven ESF pumps and the electrical areas. The cooling medium for these fan coil units is chilled water, which is supplied by the nuclear safety Chilled Water System.

High-Pressure Chemical Feed Room Ventilation System (HPCFVS)

The HPCFVS is designed to provide adequate ventilation to Room 100 to maintain the equipment below its design qualified temperature during LOOP and LOCA. The HPCFVS consists of Class 1E power supply, safety related and seismically supported supply and exhaust fans. The supply fan is provided with two in-line gravity dampers upstream of the fan and ductwork to distribute outside air to the room. The exhaust fan is provided with two in-line gravity dampers downstream of the fan to exhaust air directly from the room to the outside. The HPCFVS is required to operate when train “B” class 1E power source is utilized, and the temperature inside the room increases as a result of heat dissipated from the MCC located in this room. The HPCFVS is to be started and stopped automatically by a temperature indicating switch (TIS) which senses and indicates the room temperature.

During all modes of plant operation, the HPCFVS will be in a standby mode. Room 100 will be maintained at a slightly negative pressure. However, when the HPCFVS is energized, the supply air to Room 100 is greater than the exhaust air to ensure the room is maintained at a positive pressure. The excess air will be exhausted through the primary plant exhaust system ductwork. The exhaust fan will trip if the supply fan fails to run.

Boundary

Containment Ventilation Systems

Nuclear safety related components in the Containment Ventilation Systems that are included in this SAMR are those that support the 10 CFR 54.4(a)(1) intended functions discussed below. nuclear safety related components in the Containment Ventilation Systems are those that maintain the pressure boundary of Containment starting downstream from, and including, the Containment isolation valves associated with the containment purge supply lines, and upstream of, and including, containment isolation valves associated with Containment purge exhaust lines and Containment pressure relief lines.

The NNS filter housings of the Containment preaccess filtration unit for each CPNPP unit up to the deluge supply and drain valves, and associated loop seal piping, for the unit are also within the evaluation boundaries. NNS components of the Containment Ventilation Systems with the potential to affect nuclear safety related components in the Containment through spatial interaction are also included in the evaluation boundaries. The containment recirculation cooling, neutron detector well cooling, and CRDM air handling unit cooling coils and drip pans as well as the drain connections on the Containment preaccess filtration units are within the evaluation boundaries. In addition, Class 5 piping downstream of normally closed valves and piping, orifice, and screen upstream of the Containment pressure relief penetration are within the boundaries. The NNS valve vent piping and pressure relief intake components extend to the end of the seismic extension of the connection to the nuclear safety related components and are, therefore, assigned a structural integrity (attached) function. The NNS cooling coils and associated drip pans (including the lower portion of the housing) could leak onto any nuclear safety related component in the vicinity (and are, therefore, assigned a leakage boundary (spatial) function.

Additionally, NNS components within the reactor coolant pipe penetration cooling system direct airflow outside the primary shield wall to prevent dehydration of nuclear safety related concrete components (CC).

Containment Ventilation System boundaries for LR are reflected on the LRBDs listed below:

Unit 1:

- M1-0300-LR
- M1-0300-A-LR
- M1-0301-LR

Unit 2:

- M2-0300-LR
- M2-0300-A-LR
- M2-0301-LR

Common:

- None.

Control Room Area Ventilation System

Nuclear safety related components in the control room area ventilation system are those that support the 10 CFR 54.4(a)(1) intended functions discussed below. These are the components downstream of, and including, the southside and northside outside air intake dampers to the ventilation exhaust connection at the roof. This includes all control room area ventilation components except the humidifier packages on the control room A/C units. The control room emergency filtration/pressurization units include deluge and drain valves.

NNS components in the control room area ventilation system evaluation boundaries with the potential to affect nuclear safety related components include the discharge piping from nuclear safety related relief valves for the control room A/C unit condensers, and the supply piping to the humidifiers for the control room A/C units. The NNS relief valve discharge piping extends to the end of the seismic extension of the connection to the nuclear safety related relief valves and is, therefore, assigned a structural integrity (attached) function. The NNS supply piping to the humidifiers could potentially leak onto nuclear safety related components in the vicinity (outside the control room air conditioning units) and is, therefore, assigned a leakage boundary (spatial) function.

The Control Room Area Ventilation System boundaries for LR are reflected on the LRBDs listed below:

Unit 1 / Common:

- M1-0304-LR
- M1-0304-A-LR
- M1-0304-B-LR
- M1-0304-C-LR

Unit 2:

- None.

Miscellaneous Ventilation Systems

Nuclear safety related components in the Miscellaneous Ventilation Systems are those that support the 10 CFR 54.4(a)(1) intended functions discussed below. These components include the:

- Exhaust fans, dampers, ductwork, tubing, and valves for the battery rooms;
- Exhaust fans, dampers, ductwork, tubing, and valves for the DGAs;
- Ductwork and isolation dampers in the MS and feedwater piping area;
- Dampers, ductwork, and fan coil units in the electrical area of the SGB;
- Exhaust dampers and fans for the SWIS;
- Volume control dampers and upstream ductwork from the roof that supply the uncontrolled access area of the AB;
- UPS A/C units, associated condenser, booster fans, dampers, ductwork, and associated piping, tubing, and valves;
- Accumulator for the CCW return pressure control valve actuator from the UPS A/C unit condenser; and
- UPS room fan coil units.

NNS components with the potential for age-related degradation to affect safety related components in the vicinity of the Miscellaneous Ventilation Systems are the cooling coils, and associated drip pans and supply and drain connections, for the MS and feedwater piping area, office and service area A/C units, and uncontrolled access area A/C unit, as well as the R-12 piping associated with the condensers for the uninterruptible power supply A/C units downstream of the nuclear safety related relief valves, conservatively up to the roof exhaust. The NNS cooling coils, drip pans and supply/return piping contain water and are, therefore, assigned a leakage boundary (spatial) function. UPS A/C unit condenser relief valve discharge piping extends to the end of the seismic extension and is, therefore, assigned a structural integrity (attached) function.

Miscellaneous Ventilation Systems LR evaluation boundaries are shown on the following LRBDs:

Unit 1 / Common:

- M1-0302-LR
- M1-0302-B-LR
- M1-0304-01-LR

- M1-0305-LR
- M1-0305-A-LR
- M1-0312-LR
- M1-0313-LR

Unit 2:

- M2-0302-LR
- M2-0302-B-LR

Primary Plant Ventilation Systems

Nuclear safety related components in the primary plant ventilation systems are those that support the 10 CFR 54.4(a)(1) intended functions discussed below. The nuclear safety related components include:

- Fan coil units (emergency/room area coolers) for the motor driven auxiliary feedwater pump rooms, CCW pump rooms, CCP rooms, containment spray pump rooms, RHR pump rooms, SI pump rooms, and SFP heat exchanger and pump rooms;

- Dampers, ductwork, and fans for the high-pressure chemical feed rooms in the AB;

- Dampers, ductwork, exhaust fans and exhaust filter units from the AB, FB, and SGB to the exhaust plenum;

- Gravity dampers associated with the primary plant and AB ventilation equipment room supply.

The primary plant ventilation ESF and non-ESF filtration units also are equipped with FP deluge supply and drain valves for potential fires in the charcoal filters.

NNS components in the plant ventilation systems with the potential for age-related degradation to affect safety related components in the vicinity through spatial interaction are the cooling coils, and associated drip pans, supply/return and drain connections, for the primary plant ventilation supply, AB equipment room supply, and the positive displacement charging pump room fan coil units, and the drip pans (including lower portion of the housing for emergency room coolers). These NNS components are, therefore, assigned a leakage boundary (spatial) function.

Primary plant ventilation systems (including AB, FB, and SGB) boundaries for LR are reflected on the LRBDs listed below:

Unit 1 / Common:

- M1-0302-A-LR
- M1-0302-C-LR
- M1-0303-B-LR
- M1-0303-C-LR
- M1-0303-01-LR

- M1-0309-LR
- M1-0309-A-LR
- M1-0309-B-LR

Unit 2:

- M2-0302-A-LR
- M2-0302-C-LR

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The Containment Ventilation Systems provide primary containment pressure boundary and isolation. The Containment isolation valves in the Containment Ventilation System isolate on an isolation signal.

(2) The control room area ventilation system maintains emergency temperature limits within areas containing nuclear safety related components. The control room area ventilation system maintains the control room environment for personnel comfort and ensures that a temperature of 104°F is not exceeded for equipment concerns.

(3) The control room area ventilation system maintains a habitable environment in the event of a radiological emergency by maintaining the control room at a positive differential pressure with respect to adjacent areas in order to limit unfiltered inleakage to the CRE, providing filtered make up air, and filtering recirculation air.

(4) The Miscellaneous Ventilation Systems maintain an acceptable environment for the operation of nuclear safety related equipment to ensure operability of that equipment.

(5) The primary plant ventilation systems maintain an acceptable environment for the operation of nuclear safety related equipment to ensure operability of that equipment.

(6) The primary plant ventilation systems minimize the spread of airborne radioactivity or contamination from portions of the FB, AB, and SGB and filters the effluent prior to release to the environment under accident conditions.

(7) The primary plant ventilation systems maintain portions of the FB, AB, and SGB at a negative differential pressure with respect to adjacent areas in order to limit spread of airborne radioactivity under accident conditions.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) The Containment Ventilation System contains non-safety related water-filled lines in the Containment structure that have the potential for spatial interactions (spray or leakage) with nuclear safety related SSCs.

(2) Portions of the Containment Ventilation System include NNS piping that is in scope to provide structural support for nuclear safety related piping.

(3) NNS portions of the Containment Ventilation System (i.e., the reactor coolant pipe penetration cooling system) are designed to dissipate heat conducted to the supports by the reactor coolant lines utilizing forced convection to prevent dehydration of concrete.

(4) The control room area ventilation system contains NNS water-filled lines that have the potential for spatial interactions (spray or leakage) with nuclear safety related SSCs.

(5) The control room ventilation system contains NNS equipment that are attached to nuclear safety related SSCs and provide structural support to those SSCs.

(6) The Miscellaneous Ventilation Systems contain NNS water-filled lines that have the potential for spatial interactions (spray or leakage) with nuclear safety related SSCs.

(7) The Miscellaneous Ventilation Systems contain NNS equipment that are attached to safety related SSCs and provide structural support to those SSCs.

(8) The primary plant ventilation systems contain NNS water-filled lines that have the potential for spatial interactions (spray or leakage) with safety related SSCs.

(9) The primary plant ventilation systems contain NNS equipment that are attached to safety related SSCs and provide structural support to those SSCs.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) The Containment Ventilation System is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48). The preaccess filtration units’ containment charcoal filter units have a deluge system installed to extinguish fires in the charcoal filter trays installed in these filter units. The Containment Ventilation System must maintain FP system pressure boundary.

(2) The Containment Ventilation System is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the

Commission’s regulations for EQ (10 CFR 50.49). Components in the system provide Containment isolation following a LOCA.

(3) The control room area ventilation system is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48). The control room area ventilation system filtration units’ charcoal filter units have a deluge system installed to extinguish fires in the charcoal filter trays installed in these filter units. The control room area ventilation system must maintain FP system pressure boundary.

(4) The control room area ventilation system is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the commission’s regulations for SBO (10 CFR 50.63). The control room area ventilation system is relied upon to provide temperature control for the control room area during a SBO event.

(5) The Miscellaneous Ventilation Systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48). The plant ventilation systems are required to operate to maintain acceptable environments for required Fire Safe Shutdown equipment.

(6) The Miscellaneous Ventilation Systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for EQ (10 CFR 50.49). The Miscellaneous Ventilation Systems include components that are nuclear safety related and in a harsh environment and therefore, are environmentally qualified.

(7) The Miscellaneous Ventilation Systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48). The plant ventilation systems provide sufficient ventilation to keep the hydrogen content in the battery rooms below the lower flammability under accident conditions.

(8) The primary plant ventilation systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for FP (10 CFR 50.48). The plant ventilation systems are required to operate to maintain acceptable environments for required Fire Safe Shutdown equipment.

(9) The primary plant ventilation systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for EQ (10 CFR 50.49). The primary plant ventilation systems include components that are nuclear safety related and in a harsh environment and therefore, are environmentally qualified.

2.3.3.9. Potable and Sanitary Water System

Description

Chlorination

The purpose of the Chlorination Systems (CLSs) is to inject sodium hypochlorite and sodium bromide as required into the SSW. The CLSs are ancillary systems required for normal operation.

Potable and Sanitary Water

The purpose of the Potable and Sanitary Water System (PWS) is to distribute potable water to the plant and associated support structures and buildings for both Unit 1 and Unit 2. The water is supplied by the Somervell County Water District public water system. Domestic wastes generated on-site are transferred to and treated in, the domestic waste treatment facility. Domestic waste treatment effluent is treated with high intensity ultraviolet light for disinfection and odor reduction and is discharged to the Squaw Creek Reservoir in accordance with regulatory agency permitted effluent limits.

Boundary

Chlorination

Scoping boundaries are shown on LRBDs M1-0233-LR and M2-0233-LR. The CLS includes Class 5 process tubing that enters the SWIS. However, the CLS process tubing that enters the SWIS is encased in either PVC or metallic piping which prevents leakage or spray onto nuclear safety related components. The PVC piping is considered to have a 10 CFR 54.4(a)(2) leakage boundary function as it prevents the process tubing from leaking or spraying onto nuclear safety related components. The metallic piping encasing the process tubing is a penetration sleeve which acts as a fire barrier, a 10 CFR 54.4(a)(3) function, is subject to AMR, and is addressed in Section 2.4.15.

Potable and Sanitary Water

Scoping boundaries are shown on LRBD M1-0227-001-LR. Scoping boundaries include the portions of the system within the ECB. Within this building, potable water supply piping supplies the computer room air handling units, technical support center air handling units, and control room a/c unit humidifiers. Not included within scoping boundaries is the domestic water storage tank and connected piping, which has been abandoned in place.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) None.

2.3.3.10. Process and Effluent Radiological Monitoring and Sampling System

Description

The Process and Effluent Radiation Monitoring And Sampling Systems consist of both monitoring and sampling subsystems. The monitoring subsystems determined to be within the scope of LR are collectively referred to as the Process Radiation Monitoring System (PRMS). The sampling subsystems within the scope of LR are called the Process Sampling System (Primary) (PSS), the Post-Accident Sampling System (PAS), and the Secondary Plant Sampling System (SSS). The system descriptions that follow describe in-scope portions of the PRMS and sampling systems.

The PRMS provides a means for measuring and controlling radioactive process streams and effluents throughout the plant. The PRMS aids in ensuring the protection of the general public and plant personnel from exposure to radiation or radioactive materials in excess of those allowed by applicable regulations or governmental agencies. The design objectives of this system for normal operation are as follows:

1. To provide continuous indication and on-demand record of radiation levels, and automatic record of alarms in process and effluent streams over the range from clean-plant background to levels commensurate with TS limits.

2. To provide data useful in reporting total released activity.

3. To give early warning of increasing levels of radioactivity in process and effluent streams by using an alert-alarm set point.

4. To give an alarm and initiate a control function, where appropriate, upon high radiation levels in plant process and effluent streams using a high-alarm set point.

5. To give an indication that there is a monitor malfunction, equipment failure, or loss of counts by using a channel signal valid data check. If the test is negative, a “fault” alarm is initiated.

The PRMS includes the liquid process and effluent radiation monitors, which include CCW, service water, SG blowdown sample, TB sump effluent, liquid waste effluent, waste gas, condenser off-gas, failed-fuel, and AB to low volume waste (LVW) monitors.

These monitors serve in conjunction with varied portable and mobile monitoring equipment as well as with a comprehensive sampling program. The sampling program is the primary method for quantitatively and qualitatively evaluating process system and effluent activity levels.

In the event of a radiation release, the PRMS can provide immediate information about the concentration and dispersion of radioactivity throughout the plant, enabling operating personnel to evaluate the severity and to mitigate the consequences. For some anticipated operational occurrences resulting primarily from operator error and under certain conditions where radiation levels exceed set points, the Radiation Monitoring System (RMS) automatically actuates necessary valves and thereby limits the consequences of the release.

Continuous radiation detection and/or periodic sampling capabilities is provided for all liquid and gaseous effluent paths from which detectable quantities of radioactivity can be released from the plant during normal operation, including anticipated operational occurrences and accidents. Effluent sampling of all potentially radioactive liquid and gaseous effluent paths is conducted on a regular basis to verify the adequacy of effluent processing to meet the discharge limits. In general, the effluent sampling program requires that stored wastes be sampled and analyzed prior to release to the environment, and that potentially radioactive, continuously released effluents be periodically sampled and analyzed.

Monitors are also provided that detect excessive radiation levels as part of process monitoring and sampling.

If radiation levels in the liquid discharge lines exceed predetermined monitor set points, the monitor trips, and initiates closure of the discharge isolation valve to terminate release. If radiation levels in the Primary Plant Ventilation System exceed predetermined monitor setpoints, the monitor trips and initiates closure of the gaseous waste processing system release valve.

Process streams of the various subsystems of the Liquid Waste Processing System have monitors that are augmented by a sampling system, and this combination provides radiation monitoring to determine changing levels of system radioactivity and equipment performance.

The Process and Effluent Radiation Monitoring And Sampling Systems are made up of multiple systems that contain components subject to AMR. These systems are listed below:

- Process Sampling System
    - Process Sampling Primary Plant System (PSS)
    - Post-Accident Sampling System (PAS)
- Secondary Plant Sampling System (SSS)
- Radiation Monitoring System (RMS)
    - Containment Atmospheric Monitoring System (AMS)

The description for each system is given below.

Process Sampling System (Primary)

The PSS facilitates obtaining representative liquid and gas samples at controlled temperatures and pressures for laboratory analysis and the monitoring of chemical and radiochemical conditions. The system primary function is NNS. Only portions of the system interfacing with nuclear safety related systems and containment penetrations are nuclear safety related. Other portions of the system including the sampling and analysis panels and the sample coolers perform no safety function but are required for normal operation.

The PSS processes samples from the RCS, SIS, RHRS, CVCS, and the SG blowdown system. The PSS also includes a sample station for various demineralizers in the AB.

Post-Accident Sampling System

PAS functional requirements have been eliminated based on License Amendment 91. The system has been placed in lay-up in accordance with plant procedures; however, components in this system are in-scope due to not being physically isolated and passing through nuclear safety related buildings with nuclear safety related equipment in the vicinity. The PAS is shown on M1-0228-01-LR (reactor coolant) and M1/2-0301-A-LR (containment air). The PAS consists of two NNS subsystems for the representative sampling of reactor coolant, containment sump and containment atmosphere following an accident. The equipment within the PAS acts as a barrier to route radioactivity to a centralized location where samples are taken and transferred under controlled conditions for analysis. The system also provides for the controlled routing of purge flows to process systems, and the conditioning of samples prior to collection.

The containment isolation valves, containment penetrations and piping, and the PAS isolation valve control panel are designated Seismic Category I. All other equipment and piping are NNS.

Secondary Plant Sampling System

The SSS is provided to monitor water chemistry in condensate, SG feedwater, SG blowdown, main and auxiliary condensers, condensate polishing, heater drains, CST, vacuum deaerator, MS, atmospheric drain tank #1, and the demineralized water storage tank. The main panel is a factory assembled; skid mounted package located at EL. 778-ft in the ECB. Additional remote sample stations are located in the plant and send analyzer signals back to the main panel.

The main sample conditioning and analysis panel consists of wet and dry sections. The wet section contains the sample coolers, high-pressure regulators, the isothermal bath, and automatic in-line analyzers. The sodium, chloride, dissolved oxygen, and pH monitors are also in the wet section of the panel as they are required to process system flow. The dry section contains annunciators, recorders, hydrazine and pH controllers, and pH monitors with associated electronic circuitry.

The system is required for safe normal operation of the plant and is classified NNS. The system is not required for safe shutdown of the plant or to function after a seismic event. Piping that is located in Seismic Category I structures is designated NNS, piping Class 5.

Only a small portion of this system is in-scope for LR as shown on the M1/M2-228 series LRBDs.

Radiation Monitoring System

The primary function of the RMS is to provide for the radiological health and safety of workers in the plant and the members of the general public offsite, by detecting and measuring the radiation levels in general access areas, process equipment streams, and effluent release points. When an area monitor measures a preselected level of radiation, it will provide visual and audible warnings locally, in the control room and certain other remote readout locations via the plant computers. If high radiation levels are detected in normal effluent batch releases, the RMS causes the release to be terminated. In the case of accident conditions, the RMS will initiate certain mitigative actions and continue to monitor the radiation levels and releases to provide data for emergency response.

The RMS is a nuclear safety related system. It contains both nuclear safety related and NNS portions and interfaces with both nuclear safety related and NNS systems.

Containment Atmospheric Monitoring System

The AMS is a subset of the radiation monitoring system and has nuclear safety related designated components. The AM mechanical system is comprised of capillary tubing and bellows.

<u>Boundary</u>

The assigned systems boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0222-LR
- M1-0222-A-LR
- M1-0222-B-LR
- M1-0228-LR
- M1-0228-A-LR
- M1-0228-B-LR
- M1-0228-C-LR
- M1-0228-001-LR
- M1-0228-002-LR
- M1-0301-A-LR

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

Process Sampling System (consisting of the PSS and PAS systems)

(1) The PSS supports the containment pressure boundary.

Secondary Plant Sampling System

(2) None.

Radiation Monitoring System (including the Containment Atmospheric Monitoring System)

(3) Support monitored nuclear safety related systems pressure boundary.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

Process Sampling System

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

Secondary Plant Sampling System

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

Radiation Monitoring System (including the Containment Atmospheric Monitoring System)

(1) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

Process Sampling System

(1) Relied upon in the safety analysis and plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49).

Secondary Plant Sampling System

(2) None.

Radiation Monitoring System (including the Containment Atmospheric Monitoring System)

(3) None.

2.3.3.11. Spent Fuel Pool Cooling and Cleanup System

Description

The Spent Fuel Pool Cooling and Cleanup System (SFS) is designed to remove decay heat generated by spent fuel assemblies stored in the SFPs and to maintain the clarity and purity of water in the SFPs, transfer canal, wet cask pit, RWST, and the refueling cavities. The SFS is also designed to ensure the spent fuel assemblies remain covered with water during all storage conditions.

The SFS consists of two redundant cooling loops, two purification loops, one SFP skimmer loop, two refueling cavity skimmer loops, two refueling water loops, and one transfer canal and cask pit drain path. The cooling loops are designed to remove long-term decay heat generated from spent fuel assemblies stored in the SFPs. The purification loops are designed to control and maintain clarity and purity of water in the SFPs, transfer canal, cask pit, refueling cavities, and RWSTs. Temporary equipment is used during refueling operations in lieu of the permanently installed refueling cavity skimmer loops.

The major cooling components are located in the FB. Each cooling loop includes a pump, heat exchanger, and associated piping, valving, and instrumentation. Heat is transferred via the SFP heat exchanger to the CCW System. During heat removal operations, a portion of the SFP water may be diverted through a demineralizer and filter in either of the purification loops to maintain SFP water clarity and purity. SFP cooling water is discharged back into the SFPs via fours spargers (two per pool). Each return line has a hole in it to prevent siphoning water to a level less than one-ft below normal SFP water level.

The major purification components are located in the AB. Two purification loops are Provided for removal of fission products and other contaminates by means of filtration and ion exchange. Each purification loop is capable of purifying flow from either the SFP cooling pumps or the refueling water purification pumps. The purification loops provide for cleanup of water in the RWST, refueling cavities, transfer canal, and the cask loading pits.

To further assist in maintaining water clarity in the SFPs, the water surface is cleaned by a skimmer loop. Water is removed from the surface by the skimmers, pumped through a strainer and filter, and then returned to the pool at remote locations from the skimmers. Each SFP skimmer filter return line to the SFPs has a hole in it to prevent siphoning.

To allow maintenance of the fuel transfer equipment, the transfer canal is drained by the cask pit and transfer canal drain pump. The transfer canal water is pumped through the purification loop and discharged into the RHUT, which is part of the BRS. After maintenance, an auxiliary discharge is provided in the BRS to return water to the refueling transfer canal using the recycle evaporator feed pumps.

The cask pits are drained in a similar manner. The cask pit and transfer canal drain pump impels the water through the purification loop and into the RHUT and returns water to the pits by way of the recycle evaporator feed pumps.

A secondary function of the SFS is to form a small portion of a boron recycle crosstie flow-path between the BRS and the SIS for each unit. This Y-shaped flow path allows the efficient transfer of RHUT water to either RWST.

Refueling gates divide the fuel transfer and storage areas and help to ensure the minimum required depth for SFP cooling is maintained for fuel stored or in transit.

Boundary

Boundaries for the SFS cooling loops start at the suction screens in the SFPs. Water from the SFPs travels through the Cheng rotation vanes, the SFP cooling water pumps, the SFP heat exchangers, and then returned to the SFPs via spargers located six-ft above the fuel assemblies.

Make-up water from the Unit 1 and Unit 2 reactor make-up water storage tanks is added to the SFS via the SFP cooling water pumps.

Make-up water from the Demineralized Water System is added to the SFS via the SFP cooling water pumps.

The SFS boundary with the CCW System ends at, and includes, the inlet and outlet nozzles for CCW to the SFP heat exchangers.

Water from the RWSTs can be clarified in the SFS purification loops with suction to the refueling water purification pumps via the RWSTs to refueling water purification pump suction crosstie piping. Clarified water is returned to the RWSTs from the SFS.

Spent resins from the purification loop demineralizers are discharged to the Liquid Waste Processing System from the SFS.

The process sampling subsystem provides for sampling and monitoring of the SFP demineralizer outlet chemistry. Sample connections are provided in lines from the SFP demineralizers to PSS.

Contents from the RHUT are pumped to the SF purification loop in lines from BRS to refueling water purification pump suction crosstie piping and returned back to the RHUT. The recycle evaporator feed pump in the BRS System is used to transfer water back to the fuel transfer canal or wet cask pit.

Water remaining in the refueling cavity at the end of refueling operations is drained to the reactor coolant drain tank pumps through waste processing system valves and returned to the purification loop via Waste Processing System valves.

Components and piping in the cooling loops, the two spent fuel demineralizers in the purification loops, and piping for refueling cavity drains are designed in accordance with ASME Section III, Class 3. Portions of SFS piping and valves which penetrate containment walls are designed per ASME Section III, Class 2. The remaining components and piping of the SFS are classified as NNS and designed in accordance with ANSI B31.1 Power Piping. The boundary between safety class piping and NNS class piping appears on LRBDs as safety class 3 to piping class 5 transition except on vent, drain and test lines which are NNS downstream of the root valve. The boundary between safety class 2 piping at containment penetrations to class 5 NSS piping is depicted on the LRBDs.

Other components within the system evaluation boundaries include those components associated with the SFP cooling loops, purification loops, and surface skimmer loop.

The SFS boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0235-LR
- M1-0235-01-LR
- M1-0235-02-LR

Unit 2:

- M2-0235-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Remains functional during and following DBEs to prevent significant reduction in fuel storage coolant inventory.

(2) Provides primary containment pressure boundary. The fuel transfer tube, purification loop piping, refueling cavity skimmer pump discharge, and refueling cavity drain lines penetrate primary containment.

(3) Removes heat generated by stored spent fuel elements from the station's SFPs to maintain stored fuel within acceptable temperature limits.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in the safety analysis and plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). There are SFS components designed to accommodate and be compatible with post-accident environmental conditions in order to maintain their intended function.

2.3.3.12. Station Service Water System

Description

The purpose of the SSW is to supply cooling water to meet the plant cooling requirements during normal operation, shutdown, during or after a postulated DBA, and during all postulated DBE.

Therefore, the SSW furnishes a reliable and continuous supply of cooling water to the CCW heat exchangers, SI and CCP lube oil coolers, diesel generator jacket water coolers, and the containment spray pump bearing coolers and service water pump motor bearing coolers and pump bearings. In addition to the cooling function, the SSW is designed to provide the auxiliary feed water (AFW) pumps with a long-term source of water.

The SSW also performs the NNS function of supplying the Service Water CLS water requirements and the traveling screen wash pump water requirements.

The SSW consists of two separate and independent full-capacity, nuclear safety related trains. Cross connections between the two trains add operational flexibility to the SSW. The nuclear safety related trains are redundant in that the components supplied by one train are sufficient to perform the minimum required safety functions.

A cross connection between Unit 1 and Unit 2 SSW is provided. However, there is no sharing of any safety related component or safety related function between the two units. General Design Criteria 5 is satisfied by a single locked closed valve in the cross-connection provided between units.

SSW is pumped from the SSI, which is the UHS, and returned to the SSI through a discharge chute structure after picking up waste heat from various nuclear safety related cooling systems. The SSI is an enclosed body of water formed from a cove of the SCR and is retained by a Seismic Category I dam. SSI water enters the SWIS through the trash racks and traveling screens and is chlorinated in the SWIS. A liquid biocide is also added to the SSI water for Asiatic clam control. The traveling screens are periodically washed with service water taken from the discharge of the service water pumps. The screen wash system consists of two horizontal screen wash pumps which supply water to the travelling screen spray headers which wash the travelling screens.

Two full capacity SSW pumps and two full capacity supply and return headers are provided for each unit. These pumps are 24-in, 2-stage, vertical wet pit pumps. Both pumps normally operate. This provides continuous cooling water supply to the two redundant nuclear safety related trains. The service water pump bearings are lubricated by service water taken from the pump discharge line. This water passes through a set of two "Y" type strainers, installed in series, prior to entering the service water pump bearings.

The 24-in diameter pump discharge headers are enlarged to 30-in diameter prior to leaving the SWIS. The four 30-in underground SSW lines rise to EL. 804-ft 3-in in the yard area (below the ground level EL. 810-ft). Prior to entering the FB, the 30-in headers drop at a 45 degree angle to different levels and are stacked vertically. The headers then enter the FB through watertight sleeves. Upon leaving the FB and entering the AB, a 10-in diameter pipe is branched off of each header. After the branch-off, the 30-in headers are reduced to 24-in and connect to the nozzle of the tube side of the CCW heat exchangers. Each train is connected to one full size CCW heat exchanger. The outlet header from each heat exchanger has a flow limiting orifice and a gear operated butterfly type shut-off valve. A flow measuring element is installed in each header upstream of the butterfly valves. This outlet header then enters the FB. Before entering the FB, each 24-in header is enlarged to 30-in and the 10-in return pipe is converged into the header. The piping then enters and exits the FB through watertight sleeves. From this point the supply and return headers run parallel to each other in the pipe tunnel and in the yard for approximately 500-ft where the return headers diverge and continue to the concrete stilling basin which discharges into the service water discharge canal that connects to the SSI.

A separate 10-in line branches from each of the main 30-in SSW supply headers upstream of the CCW heat exchangers and runs through the AB and SGB. Train A and Train B are separated by about eight-ft and run in the same corridor of the AB and SGB. In the AB a 2-in branch from the 10-in line supplies cooling water to the CCPs lube oil coolers. In the SGB, Train A and Train B branches supply cooling water to the SI lube oil coolers and containment spray pumps bearing coolers. The lines then run through a pipe tunnel to supply cooling water for the diesel generator jacket water coolers. Rising through pipe chases in the DBG, the pipes connect to the jacket water cooler inlet nozzles. The 10-in pipes run through the SGB corridor where they connect to the auxiliary feedwater pump emergency suction. The return lines join the SSW discharge headers downstream of the CCW heat exchangers.

Boundary

In-scope components in the SSW are those that maintain the pressure boundary of the system starting from the SSW pumps (downstream of the trash racks and travelling screens) and associated piping and valves including the set of strainers that are used to lubricate the service water pump bearings, up to the interface with the CCW heat exchangers, the CCP lube oil coolers, the containment spray pump bearing coolers, SI pump lube oil coolers, and the EDG jacket water coolers and all associated piping, valves, and strainers. Additionally, the piping up to the interface with the AFWS and the service water discharge canal are also part of the SSW and are included in the scope of LR.

There are in-scope NNS components such as piping, floor drains, drip pans and grab sample sinks which are shown on the LRBDs.

Individual cooling units or heat exchangers supplied by the SSW are not included in this system.

The SSW boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0233-LR
- M1-0233-A-LR
- M1-0234-LR

Unit 2:

- M2-0233-LR
- M2-0233-A-LR
- M2-0234-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Supplies cooling water to meet the plant cooling requirements during normal operation, shutdown, and during or after a postulated DBE

(2) Transfers heat to the UHS or SSI

(3) Provides auxiliary feedwater pumps an alternate, long-term source of water

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Contains components relied upon to perform a function that demonstrates compliance with regulations for EQ (10 CFR 50.49)

(2) Provides cooling water to satisfy the scoping criteria of 10 CFR 54.4(a)(3) relative to regulated events such as FP (10 CFR 50.48) and SBO (10 CFR 50.63).

(3) Provides a secondary source to the Auxiliary Feedwater pumps for decay heat removal during Fire Safe Shutdown events (10 CFR 50.48).

2.3.3.13. Ventilation Chilled Water Systems

Description

Plant Ventilation Chilled Water System

The plant ventilation Chilled Water System consists of two distinct subsystems.

The first subsystem consists of six chillers, four 50 percent capacity chilled water recirculating pumps, three 50 percent capacity chilled water booster pumps, a chilled water surge tank, chilled water cooling coils, and associated piping, valves, and instrumentation. Four chillers are located in the AB and two chillers are located in the Unit 1 TB. The chillers located in the AB are of the centrifugal type with hermetically sealed, electric-motor-driven compressors. The chillers located in the TB are of the centrifugal type with open electric motor driven compressors. The pumps are electric-motor-driven, single stage, centrifugal type. The evaporators of the six chillers are connected in series. The four chilled water recirculating pumps are connected in parallel, as are the three chilled water booster pumps. This subsystem is operated to support simultaneous operation of, mainly, the containments of Unit 1 and Unit 2, which includes normal operation, reactor startup, normal reactor shutdown and reactor hot standby during a LOOP.

During reactor startup, normal operation, and normal reactor shutdown, operators will run a sufficient number of chillers to maintain ambient area temperatures within required limits.

Additionally, two out of four chilled water recirculating pumps and two out of three chilled water booster pumps are required to operate.

The equipment served by this subsystem is as follows:

- Three out of four containment air recirculation and cooling units
- One out of two containment neutron detector well cooling units
- Containment CRDM cooling unit
- Positive Displacement Charging Pump Room fan coil unit
- Secondary plant sampling package
- TB Switchgear Area supply unit
- TB Office and Room Area fan coil units
- Instrument Air System Coolers

The CCW from the non-safeguard loops of the CCW System for both Units is used as the cooling medium for the four chillers located in the AB. The arrangement of the CCW System piping allows the condensers in a specific pair of these chillers to be connected in series. Two chillers are cooled by Unit 1 non-safeguard CCW loop; and the other two chillers are cooled by Unit 2 non-safeguard CCW loop.

The two chiller condensers in the Unit 1 TB are connected in parallel and are supplied with CW as the cooling medium.

During a LOOP, this subsystem is required to serve Unit 1 and Unit 2 containment cooling units and Unit 1 and Unit 2 positive displacement charging pump room fan coil units. It will also serve the secondary plant sampling package. Only the four chillers located in the AB and two associated chilled water recirculating pumps are required to operate. The two Unit 1 TB chillers and their associated chilled water booster pumps are isolated. The four chillers and the two chilled water recirculating pumps which are selected for operation are powered from the Standby Power System during a LOOP.

The second plant ventilation chilled water subsystem consists of three chillers, each sized for 33.33 percent of the total cooling capacity, four 33.33 percent capacity chilled water circulating pumps, a chilled water surge tank (which is shared with the first subsystem), chilled water cooling coils, and associated piping, valves, and instrumentation. The chillers are centrifugal type, with direct open, electric-motor driven compressors. The chilled water circulating pumps are electric-motor-driven, single stage, centrifugal type. The evaporators of the chillers are connected in parallel to common chilled water supply and return headers. The four chilled water circulating pumps are also connected in parallel. This subsystem is operated during normal operation, reactor startup and normal reactor shutdown only. It does not operate during a LOOP. During operation at maximum design load, all three chillers are required to operate. Additionally, three out of four chilled water circulating pumps are required to operate, with the fourth pump remaining on standby.

The equipment served by this subsystem is as follows:

- Six out of eight Primary Plant Ventilation System (PPVS) supply units
- The AB HVAC Equipment Room Supply Unit
- SGB Electrical Area supply unit
- SGB MS and Feedwater Penetration Area supply unit.
- ECB Uncontrolled Access Area supply unit.
- Instrument Air System Coolers

The condensers of the three chillers are connected in parallel and are supplied with CW as the cooling medium. The surge tank is provided to accommodate expansion and contraction within the system and to permit monitoring of the system for leakage. The makeup water to the tank is supplied from the demineralized water system.

Except for cooling units located inside the containment, instrument air system, and those for the TB Office and Room Area, all cooling coils are provided with a thermostatically controlled valve at the outlet of the coil. The thermostatically controlled valve for the TB Switchgear Area cooling coils is located at the inlet of the coils. The outlet air temperature from the coil controls the valve.

The coils for the cooling units located inside the containment, except for the CRDM cooling coils, are provided with an electric-motor-operated-on-off valve which is interlocked with the respective cooling unit fan. Flow through the CRDM coils is not affected when the fans, which can be controlled from the Control Room, are stopped.

Vent and drain connections are provided on piping and equipment where necessary to facilitate testing and maintenance operations. All major components are provided with upstream and downstream isolation valves to facilitate maintenance operation.

The system is not required to function following a DBA. During a DBA, the chilled water supply and return containment penetrations isolation valves are closed, and the system will shut down.

The chilled water is circulated through the system by the chilled water recirculating pumps and circulating pumps.

The operating pumps take suction from their respective chilled water return headers and discharge it to the evaporator sections of the associated operating chillers. The cooled chilled water, after rejecting heat to the refrigerant in the chillers, is discharged into the respective chilled water supply main. The chilled water from the supply main flows through the cooling coils of the various cooling units associated with the subsystems. The warm chilled water from the cooling coils flows via the chilled water piping back to the respective chilled water return header, which feeds the suction of the chilled water recirculating pumps, thus completing the closed system.

I&C incorporating audible and visual annunciation facilitate continuous monitoring of the system performance and alert the operator in the event of a system malfunction. To maintain constant chilled water flow, a valve located in a recirculation loop is modulated by a signal from a flow element in the first subsystem and a pressure differential controller in the second subsystem. The containment isolation valves are motor operated and are powered from the DGs.

Safety Chilled Water System

The system for each unit consists of two-100 percent-capacity hermetic centrifugal chillers, two-100 percent-capacity chilled water recirculation pumps, a chilled water surge tank, chilled water fan coil units, and associated piping, valves, and instrumentation.

The chilled water by the system is supplied to the cooling units, serving the associated rooms/ areas, as follows:

- Component cooling water pump emergency fan coil units
- Charging pump emergency fan coil unit

- SFP heat exchanger and pump emergency fan coil unit (These fan coil units are common for both units, and the piping arrangement will allow chilled water to be supplied from either the Unit 1 or the Unit 2 Chilled Water System.)
- SI pump emergency fan coil unit
- Containment spray pump emergency fan coil unit
- RHR emergency fan coil unit
- Auxiliary Feedwater pump emergency fan coil unit
- Electric area emergency fan coil units
- Uninterruptable Power Supply (UPS) Room Fan Coil Units

The chillers are of the centrifugal type with hermetically sealed, electric-motor-driven compressors. The CCW from the respective trains of the safeguards loop of the CCW System is used as a cooling media for the condensers.

The pumps are electrical-driven, single-stage, centrifugal type. The surge tank is provided to accommodate expansion and contraction within the system and to permit monitoring of the system for leakage. The makeup water to the tank is supplied from either the demineralized water system or the reactor makeup water system, with consideration given to water chemistry for the Safety Chilled Water System corrosion inhibitor. The partition in the surge tank provides separate surge volumes for each safety train. A leak in one train will not affect the other train.

Vent and drain connections are provided on piping and equipment where necessary to facilitate testing and maintenance operations. All major components are provided with upstream and downstream isolation valves to facilitate maintenance operation.

The system is required to operate during post DBA conditions. The system is powered from Class 1E safety buses. During LOOP, the power is provided from DGs.

Chilled water is circulated through each of the two closed-loop safety trains. The recirculation pump takes suction from the chilled water return line and the chilled water surge tank which connects into the return line. The recirculation pump discharges into the evaporator of the chiller. The chilled water from the evaporator enters into the supply header and passes through the fan coil units connected in parallel. The return chilled water from the fan coil units enters into the chilled water line, thus completing the closed system.

<u>Boundary</u>

The evaluation boundaries of the Chilled Water Systems are:

- From the plant ventilation chilled water surge tank connection to the DRMWS through the piping to, and including, the circulating pumps. From the pumps to the coiling coils associated with cooling units serving areas of the AB, FB, SGB, ECB, and RCB returning from these coils to the plant ventilation chilled water chiller packages and back to the plant ventilation chilled water surge tank. All associated piping, valves, and tanks within these system runs are included up to the system interfaces and where the associated piping exits buildings with areas served by the system or enters the TB.

- From the safety chilled water surge tanks connection to the DRMWS through the piping to, and including, the circulating pumps. From the pumps to the safety Chilled Water System chiller packages to the coiling coils associated with cooling units serving areas of the AB, SGB, and ECB returning from these coils back to the circulating pumps. All associated piping, valves, and tanks within these system runs are included up to the system interfaces.

The Chilled Water Systems boundaries for LR are reflected on the LRBDs listed below.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The Chilled Water Systems provide primary containment pressure boundary and isolation. The plant ventilation Chilled Water System supply and return lines supporting the cooling coils inside containment contain isolation valves that close on an isolation signal.

(2) The Chilled Water Systems remove heat rejected by nuclear safety related components to ensure those components perform the intended safety function. The safety Chilled Water System removes heat rejected by nuclear safety related ESF pumps motors and UPS equipment and electrical

switchgear to maintain ambient temperatures below component design limits within the rooms served.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) The Chilled Water Systems maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) The Chilled Water Systems maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) The Chilled Water System is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48). The safety Chilled Water System is required to supply nuclear safety related cooling units for the purpose of cooling CCW, centrifugal charging, motor-driven auxiliary feedwater (MDAFW), and RHR pump rooms and essential electrical areas.

(2) The Chilled Water System is relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63). The safety Chilled Water System recirculation pumps are required to start on a Blackout Sequence Signal.

(3) The Chilled Water Systems are relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). The Chilled Water Systems contain nuclear safety related equipment that is located, and required to operate in, a harsh environment.

Valve body	Leakage boundary (spatial) Pressure boundary

2.3.3.14. Waste Processing Systems

Description

The Waste Processing Systems (WPS) are designed to process liquid, gaseous, and solid waste while achieving the lowest reasonable radioactive release to the environment available through current technology. Liquid and gaseous wastes to be recycled within the plant are first segregated from those to be processed or shipped offsite.

The sub-systems of the WPS are described below.

Liquid Waste Processing System (LWPS)

The LWPS is designed to control, collect, process, handle, store, and dispose of liquid radioactive waste generated as the result of normal operation, including anticipated operation occurrences such as LWPS equipment malfunction, excessive leakage in RCS, and excessive leakage in auxiliary system equipment. Provisions are made to sample and analyze fluids before they are discharged. Based on this analysis, these wastes are either released under controlled conditions via the CW discharge canal or retained for further processing. The circulating waterflow serves to reduce the concentration of radioactivity in the plant effluent by diluting the LWPS discharges.

Normally, radioactive liquids discharged from the RCS are recycled or processed by the BRS, thereby limiting inputs into the LWPS. Water in the RHUT that needs to be processed is sent to the Filter/Demineralizer System (FDS).

The LWPS is designed to segregate different effluents from equipment leaks and drains according to their chemical and radiochemical properties. In addition, interconnecting piping is available to allow for operating flexibility and provide for efficient utilization of purification equipment. The system is divided into subsystems.

In the reactor coolant drain tank (RCDT) subsystem, recyclable reactor-grade effluents enter the system from equipment leaks and drains, valve leakoffs, pump seal leakoffs, loop drain leakoffs, and from other deaerated tritiated water sources inside the containment. Connections are provided for various drains and leakoffs and for cooling the PRT. This deaerated tritiated liquid is normally pumped directly to the RHUTs via the Reactor Coolant Drain Tank Heat Exchanger.

In the drain channel A subsystem, aerated tritiated liquid enters Drain Channel A through lines connected to the waste holdup tank. Sources of aerated liquid include accumulator drainage, sample room sink drains, ion exchanger, filter, pump, and other equipment drains. The Waste Evaporator Feed Pump delivers the contents of the Waste Holdup Tank through a filter to the Waste Evaporator Package, the FDS or Floor Drain Tank 3 for removal of radioisotopes and boron prior to reuse or discharge.

The drain channel B subsystem collects and processes non-reactor-grade liquid wastes. These include floor drains, equipment drains containing non-reactor-grade water, and other non-reactor-grade sources. Drain Channel B equipment includes three floor drain tanks, a common filter and evaporator, two waste monitor tanks with a common demineralizer and filter, and two additional monitor tanks.

Drain Channel C is provided to collect and process waste effluents from onsite vendor laundry, personnel decontamination showers and sinks, and surface decontamination. These liquids may be collected in the Laundry and Hot Shower Tank. Drain Channel C equipment includes a Laundry and Hot Shower Tank, strainer, and filter, two Laundry Holdup and Monitor Tanks, and a Laundry Water Head Tank.

The spent resin handling subsystem collects, handles, and processes spent resins from the primary fluid systems prior to their disposal.

Gaseous Waste Processing System (GWPS)

The GWPS stores fission gases removed from the RCS. This reduces the escape of fission gases from the RCS during maintenance operations or through equipment leakage.

The primary location from which radioactive gases are removed from the RCS is the volume control tank. Smaller quantities are received via the vent connections, from the RCDT, the PRT, and the RHUTs. The waste and recycle evaporator gas strippers are normally vented to the AB exhaust.

The GWPS is shared between Unit 1 and Unit 2. The main flow path in the GWPS is a closed loop comprised of two waste gas compressors, two catalytic hydrogen recombiners, eight gas decay tanks for normal power service and two gas decay tanks for service at shutdown and startup. The eight gas decay tanks used for normal power service can also be used to function as shutdown gas decay tanks at shutdown and startup. The system also includes a gas decay tank drain pump, four gas traps, and a waste gas drain filter. All of the equipment is located in the primary AB.

Solid Waste Management System (SWMS)

The SWMS is designed to control, collect, condition, handle, process, package, and temporarily store, prior to offsite shipment, solid radioactive waste generated as a result of normal operation, including anticipated operational occurrences. The SWMS consists of ATCOR system components and the waste baling system (WBS). The WBS has a baler located in the FB. An additional waste baler was abandoned in place in the Unit 1 RCB.

The originally installed ATCOR Radwaste Solidification System is not used and many of the components have been removed from the facility. Only those components necessary for the collection and conditioning of the various waste streams prior to discharge via the bulk disposal connections on EL. 810-ft of the FB are utilized. The major ATCOR system components which are utilized include the Waste Conditioning Tank, Waste Feeder Pumps, Emergency Waste Return Pump, Powdex Transfer Pump, CAT and their associated valves, piping, and controls.

Boundary

The WPS scoping boundaries include the LWPS Reactor Coolant Drain Tank Subsystem as shown on M1-0264-LR and M2-0264-LR. Boundaries begin at leak-off lines inside containment and continue to the reactor coolant drain tank. This includes collection points for equipment leaks, valve leakoffs, pump seal leakoffs, loop drain leakoffs, and other deaerated tritiated water sources inside containment. Included in this boundary is the circulation loop from the reactor coolant drain tank, through the reactor coolant drain tank pump, to the reactor coolant drain tank heat exchanger, and back to the reactor coolant drain tank. Not included in this boundary is the RCDT gas sample vessel, which has neither a structural integrity nor leakage boundary intended function.

The WPS scoping boundaries include the LWPS Drain Channel A Subsystem as shown on M1-0265-LR and M1-0265-001-LR. Boundaries include lines connected to the waste holdup tank from accumulator drainage, sample room sink drains, ion exchanger, filter, pump, and other equipment drains (at system transitions to “WP” as shown on the LRBDs). The waste holdup tank itself is not within evaluation boundaries as it is housed in a watertight compartment separated from nuclear safety related components. Pipe routing from the waste holdup tank, through a filter and waste evaporator package, to the floor drain system or floor drain tank are within evaluation boundaries.

The WPS scoping boundaries include the LWPS Drain Channel B Subsystem as shown on M1-0266-LR, M1-0266-001-LR, and M1-0266-A-LR. Boundaries include collection lines from non-reactor-grade liquid wastes, including floor drains, equipment drains, and other non-reactor grade sources (at system transitions to “WP” as shown on the LRBDs). Floor drain tanks collecting this liquid waste are included within this boundary. Process flow paths through the floor drain tank pump, strainer, filter, and evaporator are included within evaluation boundaries, as well as waste monitor tanks which collect process effluents.

The WPS scoping boundaries include the LWPS Drain Channel C Subsystem as shown on LRBD M1-0267-LR. Boundaries include the laundry and hot shower tank and associated pump, associated strainers and filters, laundry holdup and monitor tanks and associated pumps, and the laundry water head tank. Not included in evaluation boundaries are reverse osmosis equipment, with the exception of the feed precooler. Reverse osmosis equipment has been physically isolated from other plant equipment and abandoned in place, with the exception of the feed precooler. The reverse osmosis feed precooler has been abandoned in place but still receives chilled water and is therefore within scoping boundaries.

The WPS scoping boundaries include the LWPS Spent Resin Handling Subsystem as shown on M1-0268-LR and M1-0268-001-LR. Boundaries include collection lines to the spent resin storage tank, the spent resin storage tank itself, and spent resin sluice pump.

The WPS scoping boundaries include plant effluent holdup and monitor pumps and associated piping from the plant effluent holdup and monitor tanks, through the pumps, and to the Drain Channel B Subsystem. Not included in scoping boundaries are the plant effluent holdup and monitor tanks themselves, and connected piping located in the yard. These components in the yard are separated from nuclear safety related equipment and do not have spatial interaction concerns.

The WPS scoping boundaries include major SWMS components necessary for the collection and conditioning of various waste streams, including the waste conditioning tank, waste feeder pumps, emergency waste return pump, powdex transfer pump, chemical addition tank, and their associated valves and piping. This equipment is shown on M1-0268-002-LR.

The WPS scoping boundaries include specific sub portions of the GWPS as shown on M1-0269-LR, M1-0269-001-LR, M1-0269-A-LR, M1-0269-B-LR, M1-0270-LR, and M1-0270-A-LR. The waste gas compressor package heat exchanger and compressor package drain lines are within evaluation boundaries. Other portions of the compressor package are air/gas filled and do not have LR intended functions. The catalytic recombiner condenser, component cooling inlet and outlet piping to the condenser, and catalytic recombiner drain lines are within evaluation boundaries. Other portions of the catalytic recombiner are air/gas filled and do not have LR intended functions. Gas decay tanks and associated drain lines, including gas decay tank drain pumps and drain filters, are within evaluation boundaries. Also included within evaluation boundaries are connected lines to the gas decay tanks that have a structural integrity attached intended function. Piping isometrics detailing stress calculations are used to determine the extent of structural integrity attached piping. See the associated LRBDs for further detail.

Not included in scoping boundaries are the GWPS gas analyzer racks. These components are air/gas filled and do not have LR intended functions.

The WPS boundaries for LR are reflected on the LRBDs listed below:

Unit 1:
- M1-0264-LR

Unit 2:
- M2-0264-LR

Common:
- M1-0265-LR
- M1-0265-001-LR
- M1-0266-LR
- M1-0266-001-LR
- M1-0266-A-LR
- M1-0266-B-LR
- M1-0267-LR
- M1-0268-LR
- M1-0268-001-LR
- M1-0268-002-LR
- M1-0269-LR
- M1-0269-001-LR
- M1-0269-A-LR
- M1-0269-B-LR

- M1-0270-LR
- M1-0270-A-LR

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Maintains the reactor containment pressure boundary. The WPS includes piping that penetrates containment. The containment penetrations include containment isolation valves to assure that radioactive material is not inadvertently transferred out of containment.

(2) Maintains CCW pressure boundary. WPS heat exchangers utilize CCW and maintain the CCW pressure boundary. Waste processing coolers, condensers, and heat exchangers are serviced by the CCW System and part of its pressure boundary.

(3) Retain radioactive gases for decay. The WPS gas decay tanks and interconnecting piping and isolation valves provide holdup capacity to comply with site boundary dose requirements and commitments.

(4) Prevent flooding of nuclear safety related equipment. Safeguard building floor drain sump pumps prevent flooding of the SGB via pumping water from the sumps to the WPS floor drain tanks. WPS piping between the pumps and drain tanks aid in this intended function and is nuclear safety related.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analysis or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49).

2.3.4. Steam and Power Conversion Systems

The following systems are addressed in this section:

- Auxiliary Feedwater System (2.3.4.1)
- Condensate and Feedwater Systems (2.3.4.2)
- Main Steam, Reheat, and Steam Dump System (2.3.4.3)
- Main Turbine and Auxiliaries System (2.3.4.4)

2.3.4.1. Auxiliary Feedwater System

Description

The purpose of the Auxiliary Feedwater System (AFWS) is to provide a supply of high-pressure feedwater to the secondary side of the SGs for reactor coolant heat removal following a loss of normal feedwater. The system is also used in lieu of the main feedwater during cooldown and startup operations.

The AFWS is also an ESF system which provides a cooling source in the event of a LOCA and is used in the event of a MS line break, feedwater line break, Control Room evacuation, and SG tube rupture.

Additionally, for Unit 2, the AFWS is also designed to preclude the effects of hydraulic instability due to water hammer by supplying water to the secondary side of the SG through a separate upper auxiliary feedwater nozzle.

The system is classified as nuclear safety related and consists of ANS Safety Class 2 and 3 piping and equipment, except for the NNS condensate transfer pump and associated piping and valves used to provide makeup, recirculation, and drainage for the CST.

The AFWS is comprised of two electric MDAFW pumps and associated valves, piping, and controls and a turbine-driven auxiliary feedwater (TDAFW) pump with associated valves, piping, and controls, which is independent of the electrical power supply to the motor-driven pumps. These three pumps ensure an adequate supply of auxiliary feedwater following an accident.

All three pumps normally draw suction from the CST. A single line supplies water through a common locked-open valve to the suction of the MDAFW pumps, and a second line supplies water to the suction for the TDAFW pump. The CST has a total capacity of 500,000 gallons, wherein approximately 282,000 gallons are available for auxiliary feedwater. The rest of the tank is used as condensate storage for the Condensate System.

While the CST is the preferred water supply, another alternate supply is provided for the AFWS. The AFWS has the capability to draw suction from the SSW in the event of loss of CST. Two normally closed, key-switch activated, motor-operated butterfly valves in the SSW and three motor-operated gate valves in the AFWS prevent contamination of the auxiliary feedwater by SSW. In addition, high- and low-point leakoff connections are provided between the SSW isolation valves and the motor-operated gate valves to allow detection of any SSW in-leakage. An orifice has been installed in the leakoff lines to limit the leakage rate into the SGB.

Each motor-driven pump normally feeds two SGs. A normally closed interconnection between the motor-driven pump discharge lines permits either pump to feed to all four SGs. This interconnection provides the operator with the means to maintain the water level in all SGs on a long-term basis following a LOCA by operating either motor driven pump. The turbine-driven pump discharge line branches into four separate lines, each feeding one SG.

Each of the lines that connects the three auxiliary feedwater pumps to the SGs are provided with: a normally open, pneumatically operated feed regulator control valve; a flow-limiting orifice; a check valve; a motor operated isolation valve; and two manual isolation valves. Air accumulators are provided for the pneumatically operated valves with sufficient capacity to permit remote valve closure in the event of a secondary system break where local valve operation cannot be accomplished within the required time period following the incident. The control valves are located near each AFW pump to allow isolation or local manual flow control as required. The flow limiting orifices are provided to limit flow to any one SG to a maximum of 1380 gpm, in the event of either a main feed line break or a MS line break inside containment.

An orifice-type flow measuring device is located in each of the auxiliary feedwater lines to indicate flow to each SG and to provide a means of detecting grossly uneven flow to the SGs. To avoid the possibility of a single active failure stopping all auxiliary feedwater flow to a SG, there are no valves located in the common main feedwater lines.

Downstream of the last isolation valve, each line from the motor-driven pumps joins with a corresponding line from the turbine-driven pump to form a common line that connects with the feedwater line that connects to the auxiliary nozzle on the Unit 1 SGs. For Unit 2, this common line from the motor and turbine driven pumps connects with the feedwater preheater bypass line, which in turn connects to the auxiliary nozzle on the Unit 2 SGs.

Boundary

The AFWS boundaries for LR are reflected on the LRBDs listed below.

In-scope components in the AFWS are those portions of the system starting from the CST in the yard, through the AFW pumps located within the SGB and all associated piping, valves, moment restraints and other mechanical components up to the interface of the four-inch AFWS piping to the six-inch Feedwater inlet piping for the auxiliary feedwater nozzle for each SG. This includes the nuclear safety related accumulators and associated tubing and valves for the air-operated AFWS control valves.

The AFWS interfaces with other nuclear safety related and NNS systems at isolation valves that serve as the boundary between the systems. The only subject AFWS components that do not include an isolation valve (in one system or the other) at the (mechanical) interface are the:

- Inlet line to each SG auxiliary feedwater nozzle that is separated from other components assigned to the FWS.
- TDAFW Turbine casing which is supplied and drained by MS piping and components; and
- CST fill/makeup line overflow line to the Demineralized and Reactor Make-up Water System.

The AFWS evaluation boundaries for LR also include NNS piping and components that are attached to or located in the vicinity of nuclear safety related components. These NNS AFWS components are assigned a leakage boundary (spatial) function and include the condensate transfer pumps, piping and valves that are located in the seismic pipe tunnel and the SGB. The AFWS boundaries also include NNS lines downstream of relief or other closed valves that by design could contain water that is routed to a drain. Additionally, the LR evaluation boundaries for the AFWS are ended before condensate components enter the TB and at the interface with the CST treatment skid deoxygenation pumps and associated piping and valves.

Also, NNS AFWS components downstream of normally closed drain valves, and vent valves are attached to nuclear safety related components and are normally empty. These AFWS portions are assigned a structural integrity (attached) function and include the entire length of piping.

Unit 1:

- M1-0202-003-LR
- M1-0206-LR
- M1-0206-001-LR
- M1-0206-002-LR

Unit 2:

- M2-0202-003-LR
- M2-0206-LR
- M2-0206-001-LR
- M2-0206-002-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) The AFWS, in conjunction with the Main Steam System, transfers core decay heat, RCP heat, and sensible heat from the RCS to the UHS under accident conditions.

(2) The AFWS enables safe shutdown decay heat removal by maintaining the water levels in the SGs, and thus ensures adequate heat removal capacity, in the event of a LOCA.

(3) The AFWS serves as the emergency feedwater source during hot standby and cooldown from power operations to the RHRS cut-in conditions.

(4) The AFWS also helps to prevent leakage of fission products from the RCS into the secondary plant by maintaining the SG water levels following a LOCA.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Performs a function that demonstrates compliance with the Commission's regulations for EQ (10 CFR 50.49). Contains a large number of components such as the TDAFW pumps which are relied upon in the safety analyses and plant evaluations to remain functional in a harsh environment.

(2) Performs a function that demonstrates compliance with the Commission's regulations for ATWS (10 CFR 50.62). Receives actuation signals from the ATWS Mitigation System to start the auxiliary feedwater pumps if a reactor trip fails to occur.

(3) Performs a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48) and SBO (10 CFR 50.63). The AFWS consists of nuclear safety related air operated valves that are designed to fail open, in order to permit uninterrupted steam supply to the AFW pump turbine in the event of LOOP. The TDAFW pumps in turn facilitate auxiliary feedwater flow from the CST to the SGs to ensure decay heat removal during Fire Safe Shutdown regulated events (10 CFR 50.48) and a SBO (10 CFR 50.63).

2.3.4.2. Condensate and Feedwater Systems

Description

The Condensate and Feedwater Systems return the condensate from the turbine condenser hot wells through the regenerative feed heating cycle to the SGs while maintaining the water inventories throughout the cycle.

The Condensate and Feedwater Systems are designed to provide FW to the SGs during steady-state operation at the 100 percent NSSS power.

The condensate portion of the system is designed to supply condensate to the suction side of the SG FW pumps during steady-state operation at maximum guaranteed turbine load.

The FW portion of the system is designed to supply the FW required for various loads at steady-state operation and to maintain this flow, as required, during the steam dump conditions following a large load reduction. The system is designed to maintain uniform FW flow to all SGs under all conditions and to maintain proper SG water levels automatically during steady-state and transient conditions.

The CST is designed to store supply water for the Condensate and Feedwater Systems and is included in the AFWS.

The nuclear safety related portions of the Condensate and Feedwater Systems are the FW piping portions between the moment restraints upstream of the FW isolation valves (FWIVs) and the SG FW nozzles. These portions are designed to Seismic Category I requirements and are designed to withstand the worst anticipated environmental phenomena taken individually.

Condensate System Description

Two motor-driven, constant-speed, vertical, canned-type condensate pumps are supplied, each designed for approximately 65 percent of the total condensate flow. These pumps withdraw condensate from the two main condenser hot wells via a common discharge arrangement which cross connects the two condenser shells, minimizing level differences between the two hot wells.

Both pumps are vented to main condenser shell B to prevent air binding in the pumps. Seal and priming water are supplied to the condensate pumps from the CST. The condensate pumps discharge into a common 30-in. header, which carries the flow to the Condensate Polishing System (CPS) or to the main feed pump suction.

The total condensate flow rate is measured in the 30-in. line from the condensate pump discharge header to the condensate filter demineralizers. This measurement is made to ensure that the flow rate does not fall below the minimum flow requirements of the condensate pumps (2900 gpm per pump). Should the demands of the Feedwater System be low, the recirculation line valve upstream from the drain coolers opens, allowing the additional flow to return to the condenser.

At the outlet of the filter demineralizers, the flow divides to provide cooling water to both the main and auxiliary gland steam condensers under normal and minimum recirculation condensate flow conditions. These lines rejoin the balance of the condensate flow in the 30-in. header downstream of the main and auxiliary gland steam condensers. The flow is then divided into two approximately equal streams, each passing in succession through the tube side of the drain cooler and two stages of regenerative heating provided by FW heaters Nos. 5 and 6. A cross connection between the inlets of heaters 4A and 4B promotes equalization of temperature. The flow remains separated as it passes through the next two stages of FW heating provided by the No. 3 and 4 FW heaters.

The condensate flow is then distributed equally to the suction side of the FW pumps after passing through a flow measuring device, located in each pump suction line, used to control FW pump recirculation.

Feedwater System Description

The Feedwater System is of the closed-cycle type and receives water from the Condensate System and the heater drains systems (HDSs) (specifically, drains from heaters 1, 2, and 3, and moisture separator/reheater (MSR) drain tanks). The FW is transported through the final two stages of FW heaters to the SGs.

During power operation each SG FW pump takes suction from the Condensate System and discharges through a common header to the high-pressure FW heaters. One SG FW pump is required to operate during power operation of up to 50 percent of the rated power. From 50 percent power to full power, both SG FW pumps are required, with each pump providing 50 percent of the required flow. Prior to aligning FW pumps to the SGs, water is supplied by the AFWS.

The dual admission FW pump turbine drivers operate with steam from two sources. During low-load conditions, high-pressure steam is supplied to the FW pump turbines from the MS supply steam dump header. During normal operation, low-pressure steam is supplied from the MSR in the Main Steam Supply System. Gland steam is provided to the FW pump turbines from the Turbine Gland Steam Seal Supply System.

The flow from the two SG FW pumps combines at the pump discharge, then divides into two streams for the final two stages of regenerative FW heaters Nos. 1 and 2. The two heater trains and the common bypass join downstream of the high-pressure heaters to form a single common header for temperature equalization. From this common header, an individual FW line supplies each SG which passes through a LEFM.

When originally constructed both Unit 1 and Unit 2 incorporated a FW Bypass System on each main feedwater line to a steam generator. The function of the FW Bypass System is to minimize the potential occurrence of a water hammer in the steam generators, and to mitigate the flow induced tube vibration in the steam generators.

With the installation of Delta 76 steam generators on Unit 1, the FW Bypass System is no longer required for the new feedring steam generators and has been removed from Unit 1 with the exception of the small bypass line around the main feedwater isolation valves (FWIV). (Note: The Unit 1 FW System is operated in a different manner after RSG installation. The FWIV remain open during startup and a small flow through the valve and not the FIBV is used for purging purposes.) Unit 2 still retains the FW Bypass System in its entirety.

The Unit 2 preheater and original FW Bypass System associated with an individual Main FW line consists of three lines with associated I&C as follows.

The Unit 2 FW preheater bypass line connects each main FW line, just upstream of the main isolation valve, to the AFW nozzle in the upper portion (above normal water level) of each SG. Each bypass line has its own containment isolation valve (FW preheater bypass valve) which is air operated. The objective of this bypass line is to minimize the potential occurrence of pressure transients and to prevent FW from entering the main FW nozzle at startup and during certain other operating conditions.

The Unit 2 FW split flow bypass line connects the main feed line to the FW preheater bypass line inside containment to provide a continuous FW split flow during normal plant operating conditions in order to minimize thermal transients in the nozzle and connecting piping when flow is transferred to the auxiliary FW nozzle from the main FW line and to minimize the flow induced tube vibration in the SGs. It contains an Annubar flow element and an air operated butterfly valve.

In addition, a flow restricting orifice has been installed in each Unit 2 main FW line just downstream of the bypass line connection to facilitate the required flow split.

In addition, a small bypass line around the FWIV is provided to purge cold FW from the main FW line between the isolation valve and the SG FW nozzle. This line incorporates a restricting flow orifice and an air operated globe type shutoff valve which also serves as a containment isolation valve.

Connections from the Condensate System are provided both upstream and downstream of the heaters to permit flushing of the heaters. The upstream connection can also be used to fill the system and the SGs and to provide FW directly from the condensate pumps during the early stages of startup.

Full flow flushing of the Condensate and Feedwater Systems is provided to permit piping cleanup before plant startup. Full flow flushing is accomplished through a 24-in. diameter pipe routed from the outlet of the HP FW heaters to the condenser. Bypass lines with isolation valves are provided around each SG FW pump for use during flushing operations.

CO and FW chemistry are controlled using volatile chemical treatment in conjunction with the CPS.

Chemical feed to Unit 2 SGs is introduced at a point upstream of the AFW supply connection to the Feedwater System for adjustments to the water chemistry during SG layup periods only. Chemical feed to the Unit 1 SGs is introduced at the main FW lines which do not interface with the AFW supply connection.

Boundary

The Condensate and Feedwater Systems boundaries begin at the auxiliary feedwater condensate supply from the CST through Class 5 piping connecting to interfacing systems of Auxiliary Steam, Demineralized and Reactor Makeup Water (through the CST treatment skid), Secondary Sampling, SG Blowdown Cleanup, and Liquid Waste Processing. The in-scope boundary continues into each of the above mentioned systems. A leak or spray of treated water from the CST treatment skid piping or pumps would not challenge the intended function of the outdoor CSTs. The external surfaces of the concrete CSTs are managed by the Structures Monitoring

(B.2.3.34) AMP. Therefore, evaluation boundaries for the CST treatment skids begin at the transitions from PVC to carbon steel and stainless steel piping, leading below ground.

Additionally, the main condensers and condensate pumps, which are contained in the Condensate System are not within the scope of LR.

From the SG FW nozzles through the FW isolation valves stopping at each FW moment restraint on the outboard side. Included in these piping sections are connections with the AFWS.

From the TB/SGB interfaces downstream of each of the four FW line isolation valves up to the nuclear safety related moment restraints as well as various miscellaneous vent and drain lines and connections to interfacing chemical feed, secondary sampling, and nitrogen gas systems.

The LR boundaries for LR are reflected on the LRBDs listed below.

Unit 1:

- M1-0203-001-LR
- M1-0203-001A-LR
- M1-0204-LR

Unit 2:

- M2-0203-001-LR
- M2-0203-001A-LR
- M2-0204-LR

Common:

- None.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

Condensate System

(1) None.

Feedwater System

(2) Support containment pressure boundary by providing containment isolation capability with automatic or remote manual closure of the containment isolation valves and the secondary system sampling valves in the event of a LOCA.

(3) Provide a flowpath for auxiliary feedwater to the SGs. On Unit 2, the Feedwater System supports the AF functions by isolating the main FW lines and split-flow bypass lines.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

Condensate System

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function. The CO System includes piping located in the AB, Safeguards Building, and Control Building, which house nuclear safety related components. In addition, the Condensate System includes piping located in the yard near nuclear safety related SSCs (CST).

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

Feedwater System

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function. The FW System includes NNS piping located in Containment and the Safeguards Building, which house nuclear safety related components. Inside Containment, the portion of FW System piping in scope for 10 CFR 54.4(a)(2) are vents and drains.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function. FW System piping upstream of the moment restraints on the main FW lines and downstream of the Turbine Building to Safeguards Building interface are in scope for 10 CFR 54.4(a)(2). Inside the Safeguards Building, the portions of FW System piping in scope for 10 CFR 54.4(a)(2) are drain piping, test connections, and nitrogen supply piping.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

Condensate System

(1) None.

Feedwater System

(2) Relied upon in the safety analyses and plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for EQ (10 CFR 50.49). The Feedwater System includes components

that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(3) The Unit 2 Feedwater System is required to provide system isolation and a flow path for AFW during a SBO (10 CFR 50.63) regulated event.

2.3.4.3. Main Steam, Reheat, and Steam Dump System

Description

The purpose of the Main Steam, Reheat, and Steam Dump System (MSS) is to utilize saturated steam from the SGs for transporting thermal energy to the turbine, where it is converted to mechanical motion and then to electrical energy. The MSS is also used for providing steam for auxiliary services, SG pressure relief protection, controlled heat release from the reactor, means of limiting steam flow transients during rapid load rejection, and interface connection between the SG, SG blowdown, and PSS. The system is also used to feed the main feedwater feed pump turbines, auxiliary feed pump turbine, Steam Dump System, Turbine Shaft Seal System, and the Plant Process Steam System.

The MSS is used for plant cooldown. This is achieved by progressively lowering the pressure of the SGs; the decay heat and the sensible heat are removed by the generation of steam. When SG pressure has been reduced to 100 psia, the RHRS is placed in operation.

The MSS also includes the SG Blowdown and Cleanup System, which is used to cool, depressurize, filter, and remove dissolved solids and radionuclides by filtration and ion exchange from the SG blowdown.

The system consists of MS isolation valves (MSIV), MS safety valves, MS relief valves, turbine driven auxiliary feedwater pump steam supply isolation valve accumulator tanks and steam flow restrictor and drain pots.

During normal operating conditions, the MSS provides overpressure protection, prevents uncontrolled blowdown of the SGs, delivers steam for use in several other systems and adequate drainage for startup and saturated steam. It also is required to provide the interface connections between the SGs and the SG blowdown and PSSs.

The MSIVs are designed to stop flow from either direction within five seconds after receipt of signal to close to prevent uncontrolled steam release from more than one SG.

The SG Blowdown System (SB) is a subsystem within the MSS. During normal operation, blowdown from each SG is combined together in a common line outside the containment. The total SB flows through the tube side of the SB heat exchanger and after pressure reduction flows through the filters and demineralizers. The cooled, demineralized, low pressure blowdown is then combined with condensate and used as coolant to the SB heat exchanger. After the heat exchanger, the combined condensate and blowdown fluid is directed to the heater drain tank.

Boundary

Nuclear safety related components in the MSS are those that support the 10 CFR 54.4(a)(1) intended functions discussed below. These are the class 2 piping and components on piping runs starting downstream of the SGs to and through the moment restraints and SG sample isolation valves, as well as piping to normally closed valves and MSS safety valves in the system. Nuclear safety related components in the MSS are also those that maintain the pressure boundary of the system that are class 3 components downstream of moment restraints on drawing M1/2-0202-002-LR through both normally open and normally closed drain valves in the system.

NNS components in the MSS evaluation boundaries with the potential to affect nuclear safety related components include the include class 5 piping downstream of both normally open and normally closed drain valves, and normally closed drain and vent valves shown on M1/2-0202-003-LR. It also includes class 5 piping downstream of the moment restraints and SG sample isolation valves. This also includes class 5 piping downstream of normally closed valves and MSS safety valves in the system.

NNS components in the MSS evaluation boundaries that have a 10 CFR 54.4(a)(2) leakage boundary (spatial) intended function are SG Blowdown System components in buildings containing nuclear safety related components. This includes the SG blowdown spent resin storage tank, filter casings, spent resin sluice pump, heat exchangers, piping, and valves in buildings containing nuclear safety related components.

The LR boundaries are reflected on the LRBDs listed below.

Unit 1:

- M1-0202-LR
- M1-0202-002-LR
- M1-0202-003-LR
- M1-0239 -LR
- M1-0239-001-LR

Unit 2:

- M2-0202 -LR
- M2-0202-002-LR
- M2-0202-003-LR
- M2-0239 -LR
- M2-0239-001-LR

Common:

- None.

System Intended Functions

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provide Main Steam pressure boundary.

(2) Providing overpressure protection for the SGs and all other components within the MSS via the MSS safety valves.

(3) Preventing the uncontrolled blowdown of more than one SG via the Main steam isolation valves (MSIVs).

(4) Delivering the required quantity and quality of steam to the auxiliary feedwater pump turbine for the complete range of SG pressures required for cooldown.

(5) Providing controlled heat release from the reactor during normal and emergency plant operating conditions.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Perform a function that demonstrates compliance with the Commission’s regulations for fire protection (10 CFR 50.48). Actuation of the MSIVs is required in order to ensure decay heat removal during Fire Safe Shutdown regulated events.

(2) Relied upon in the safety analyses and plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for EQ (10 CFR 50.49). The MSS includes components that are nuclear safety related and in a harsh environment and required for DBA mitigation or post-accident and therefore, are environmentally qualified.

(3) Perform a function that demonstrates compliance with the Commission’s regulations for SBO (10 CFR 50.63). MSS safety valves are necessary to maintain decay heat removal functions during a SBO event.

2.3.4.4. <u>Main Turbine and Auxiliaries System</u>

<u>Description</u>

Auxiliary Steam

The purpose of the Auxiliary Steam System (SAS) is a shared support system designed to provide a supply of low pressure saturated steam to miscellaneous warm-up, startup, and process services in the TB and AB. The system is also required to collect and return condensate from various equipment to the steam cycle.

Chemical Feed and Hydrazine Injection

The purpose of the Chemical Feed System (CFS) and Hydrazine Injection System (HIS) are to control pH and dissolved oxygen in condensate and SG water during normal operation, hot standby, and wet layup. The primary function of the CFS is to control corrosion in the Secondary System and the SGs. Proper water chemistry in the SGs will also help control deposits in the turbine.

Circulating Water

The purpose of the CWS is to function as the heat sink for heat rejected by the turbine plant. In addition to heat removal, the system maintains the required back pressure in the main condensers and the auxiliary condensers which serve the feedwater pump turbine drivers. The system also supplies cooling water to the turbine plant cooling water heat exchanger, condenser exhausting vacuum pump heat exchangers, and the NNS ventilation chiller condensers.

Condensate Polishing

The purpose of the CPS is the removal of both dissolved and suspended solid contaminants in the condensate to minimize the build-up of sludge and corrosion products in the SG. The system water used for backwashing may be reclaimed.

Condenser Vacuum and Waterbox Priming

The purpose of the Condenser Vacuum and Waterbox Priming System (CVS) is to remove air from the vapor side of the main and auxiliary condensers during startup and normal operation, and to remove trapped air from those parts of the CW System which are above lake level. The latter function is necessary to avoid undesirable hydraulic transients during startup of the CWS and to ensure complete flooding of condenser tubes for proper heat transfer performance during normal operation.

Heater Drains

The purpose of the HDS is to aid in regenerative heating of FW by cascading the higher energy drains through successively lower energy stages of feedwater heaters. The system is also required to return the condensed water from the extraction steam to the Condensate and Feedwater Systems in a manner which results in thermodynamic cycle efficiency.

Turbine Plant Cooling Water

The Purpose of the Turbine Plant Cooling Water (TS and WS) Systems are designed to cool all turbine generator associated equipment and conventional plant equipment and systems which are classified as NNS. The system acts to remove residual heat from all turbine plant associated equipment by means of the turbine plant cooling water heat exchangers and rejects this heat to the Squaw Creek Reservoir, which acts as a heat sink.

<u>Boundary</u>

Auxiliary Steam

Scoping boundaries are shown on LRBDs M1-0213-LR and M1-0213-001-LR. Scoping boundaries include portions of the system within Seismic Category I buildings. Included in these boundaries are Auxiliary Steam supply and outlet piping to and from the floor drain, Waste Processing System, and BRS evaporator packages, as well as the CVCS boric acid batching tank. Outlet piping travels to the auxiliary steam condensate cooler, condensate sample cooler, and Auxiliary Steam drain tank. From the drain tank, drained Auxiliary Steam is pumped through auxiliary steam drain pumps out of the AB to TB Unit 1. Scoping boundaries end at the AB/TB interface.

Chemical Feed and Hydrazine Injection

Scoping boundaries are shown on LRBDs M1-0221-LR, M1-0221-001-LR, and M2-0221-001-LR. Scoping boundaries begin at each unit's reagent head tank and continue to the amine and hydrazine solution tanks. From these tanks fluid is drawn by amine and hydrazine pumps and delivered to the Feedwater System and AFWS. Scoping boundaries end at system supply interfaces with the Feedwater System and AFWS. Also included in scoping boundaries are Unit 2 chemical feed recirculation lines connected to Feedwater System supply lines the SGs. For each of the four Unit 2 SGs, chemical feed piping draws water from the Feedwater System, through chemical feed recirculation pumps, and delivers it back to the Feedwater System. Unit 1 chemical feed recirculation lines have been disconnected, drained, capped, and abandoned in place and are not within scoping boundaries, as these abandoned lines do not perform any LR intended functions.

Circulating Water

There are no CW system mechanical components subject to AMR. Circulating water pump trip logic prevents flooding of the TB, and eventually the ECB on the failure of circulating water expansion joints. As the trip logic is comprised of active mechanical components, they are not subject to AMR whereas the passive cables for this trip function are in the scope of LR, in-scope bounding approach, and subject to AMR. The passive pump casings do not support a flood barrier function and therefore are not within the scope of LR.

Additionally, a portion of the system is located inside the SWIS; however, this portion of the system is not connected to nuclear safety related SSCs and is not liquid-filled, therefore there is no leak/spray potential onto nuclear safety related SSCs. This portion of the CW system (line 30-CW-X-001-100-5) is a high point in the system, is located downstream of locked-closed valves, and has an open drain path through a sparger to the SSI.

Condensate Polishing

Scoping boundaries are shown on LRBD M1-0244-001A-LR. The majority of CPS components are located outside of Seismic Category I buildings and are outside of scoping boundaries. The only portion of the CPS within scoping boundaries is the portion within the FB. This includes inlet and outlet piping to the hot phase separator. The hot phase separator itself is not within the scope of LR. The hot phase separator is located in FB room X-272 which does not contain nuclear safety related equipment, except for an electrical cable protected by conduit, which acts as a spray shield. Therefore, the hot phase separator and other condensate polishing components located within room X-272 do not have leakage boundary intended functions and are not within the scope of LR.

Condenser Vacuum and Waterbox Priming

Scoping boundaries are shown on LRBD M1-0211-LR. The majority of condenser vacuum and waterbox priming components are located outside of Seismic Category I buildings and are outside of scoping boundaries. The portion within scoping boundaries are drain lines within the ECB. Note that the main line connected to the drain lines and directed to primary plant ventilation equipment, is air/condensation filled, and is not within scoping boundaries as it does not have a leakage boundary intended function. Also note that the Unit 2 configuration is not identical to Unit 1. In Unit 2, there are no drain line connections within the ECB. As such there are no Unit 2 portions of the CVS within scoping boundaries.

Heater Drains

Scoping boundaries are shown on LRBDs M1-0207-B-LR and M2-0207-B-LR. Boundaries only include a small portion of the HDS. This portion begins at outlet connections from the SG Blowdown System within the ECB and terminate at the ECB/TB interface.

Turbine Plant Cooling Water

Scoping boundaries are shown on LRBDs M1-0212-B-LR and M2-0212-B-LR. Scoping boundaries include portions of the system within the ECB. This includes the supply and outlet piping to and from the instrument air compressor package and air compressor heat exchanger. The heat exchanger is within the scoping boundaries of the Turbine Plant Cooling Water System, but the instrument air compressor is not. The instrument air compressor enclosure prevents leakage or spray from impacting nuclear safety related components. The components mounted within the enclosure are not in the scope of LR. The instrument air compressor enclosure is evaluated under Structural Commodities – Bulk. Included in scoping boundaries are supply and outlet piping within the AB to and from the auxiliary steam condensate cooler and sample coolers. The coolers themselves are within the scoping boundaries of the Auxiliary Steam System, and not the Turbine Plant Cooling Water System.

<u>System Intended Functions</u>

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None.

NNS components that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Maintain leakage boundary of NNS components such that no spatial interaction with nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(2) Maintain structural integrity of NNS components such that no interaction with attached nuclear safety related components could prevent satisfactory accomplishment of a safety function.

(3) Mitigate the effects of an internal flood. CW pump trip logic prevents flooding of the TB, and the ECB. Failure of the main condenser CW expansion joint can cause rapid flooding of the TB sump. Consequent flooding of nuclear safety related equipment (in the ECB) is prevented by tripping the Circulation Water Pumps before the flooding overflows the TB pit (EL. 778-ft).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) None.

2.4. SCOPING AND SCREENING RESULTS: STRUCTURES

All CPNPP Seismic Category I structures are designed to withstand the effects of natural phenomena, such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. Missiles, generated by floods, are not a design consideration as the Probable Maximum Flood (PMF) is lower than grade elevation. The SWIS is designed for tornado generated missiles, among other loads. This provides adequate protection for any low velocity waterborne object. For Seismic Category I buildings other than the RCB, the effects of venting are considered in determining the maximum pressure differential across building wall, floor, and roof systems. Reinforced concrete external roofs and walls of Seismic Category I structures form barriers against tornado generated missiles.

Nuclear safety related structures, except the SWIS and the ECB, are not subject to flooding, wave action, or wave runup and do not require flood or wave protection. The plant grade is at EL. 810-ft, and the peak SCR level is at EL. 789-ft 8-in for the PMF. The plant grade provides 20-ft 4-in of freeboard above the PMF and superimposed wave runup on Squaw Creek Reservoir. The site grade is well above the maximum water levels conceivable on the Brazos River. Hence, the site will be unaffected by river flooding of any kind and will not be affected by tsunami, seiche, or ice flooding. Although some of the Category I foundations are below the PMF level of the reservoir (EL. 789-ft 8-in), groundwater is not expected to reach higher than EL. 775-ft because of the impermeable nature of the rock.

The following structures and commodities are addressed in this section:

- Containment Building (2.4.1)
- Auxiliary Building (2.4.2)
- Diesel Generator Buildings (2.4.3)
- Electrical and Control Building (2.4.4)
- Fuel Building (2.4.5)
- Safeguards Buildings (2.4.6)
- Safe Shutdown Impoundment and Dam (2.4.7)
- Service Water Intake Structure (2.4.8)
- Switchgear Buildings (2.4.9)
- Turbine Buildings (2.4.10)
- Yard Structures (2.4.11)
- Switchyard Structures (2.4.12)
- Component Support Commodity Group (2.4.13)
- Crane/Hoist Commodity Group (2.4.14)
- Fire Barrier Commodity Group (2.4.15)

With the exception of some yard structures, these buildings and structures are shown on FSAR Figure 1.2-1. The buildings and structures that are in scope and subject to AMR are highlighted on the LRBD LR-STRUCT-01.

The evaluation boundaries, in scope of LR, for each structure includes and extends from the foundation to the roof, as applicable. The boundaries also include structural steel elements (framing) and other materials associated with the integrity of the structure, including interior compartment integrity, or that are unique to the structure (such as the

SFP in the FB). Airtight or tornado venting doors, as well as tornado blowout panels and dampers (in exterior and internal walls), are included in the evaluation boundaries of the pertinent structures since they are associated with the integrity of that structure.

2.4.1. Containment Buildings

Description

The Unit 1 and Unit 2 RCBs, including internal structures, are fully continuous, steel-lined, reinforced concrete structures which consist of a vertical cylinder with a hemispherical dome supported on a foundation mat with a reactor cavity pit projection. Each containment superstructure is independent of the adjacent interior and exterior structures. Sufficient space is provided between the containment and the adjacent structures to prevent contact under all combinations of loadings, including seismic. Each vertical cylinder has an inside diameter of 135-ft, height of 195-ft, and wall thickness of 4.5-ft. The inside radius of the hemispherical dome is 67.5-ft, and the dome has a thickness of 2.5-ft. The top of the 12-ft thick foundation mats sit approximately 4.5-ft below plant grade. Plant grade elevation is at 810-ft. The reactor cavity pit projections are each 24.3-ft deep and extend down from EL. 805-ft 6-in. The foundation mat beneath the reactor cavity pits has a bottom EL. 769-ft 2-in.

The principal reinforcement used in the mats, walls, and domes are No. 18 bars, made continuous at splices by the use of Cadweld mechanical connectors. The reinforcing steel pattern in the cylinder walls consist of vertical bars at each face, horizontal hoop bars at each face, and 45-degree diagonal bars, in each direction, near the outside faces. The foundation mats are reinforced with top and bottom layers of bars.

The RCBs completely enclose each unit’s reactor and RCS. An interior structure within each RCB supports and provides shielding for the reactors and other components of the NSSS. The containments are designed to withstand the pressures and temperatures resulting from a spectrum of LOCAs and secondary system breaks. Major components of the RCBs and internal structural components include:

- Steel Liner

  The entire inside face of each containment (mat, walls, and dome) is lined with a continuous welded steel liner plate, attached with anchors to the reinforced concrete, to ensure a high degree of leak tightness. The thickness of the wall liner is $^{3}/_{8}$-in, the dome is ½-in, and the foundation mats have a ¼-in thick plate covered with a layer of concrete. Local thickened liner plate sections are provided at penetrations, at major pipe and duct support attachments, at crane and rotating platform girder brackets, and at the bottom of the cylindrical wall’s steel liner. Overlay plates and/or structural shapes may be used on the interior side of the liner for support of minor pipes and ducts, conduits, cable trays, and equipment. Leak-chase channels are provided at liner seams which, after construction, are inaccessible for other means of leak tightness examination with the exception of threaded screw caps.

- Containment Penetrations and Attachments

  Personnel Airlock

  The personnel air lock is an approximately 9-ft inside diameter electro-hydraulically operated double-door assembly. Each door is hinged and gasketed, with leakage test taps aligned to the annulus between the gasket sealing surfaces.

  Emergency Airlock

  The emergency air lock is an approximately 5-ft 9-in inside diameter manually operated double-door assembly, with 2.5-ft diameter doors.

  Equipment Hatch

  The equipment hatch is a 16-ft inside diameter single closure penetration. The bolted hatch cover is mounted on the inside of the containment and is double-gasketed with a leakage test tap between the gaskets. The hatch cover is provided with a hoist for handling. During cold shutdown (Mode 5), refueling (Mode 6) or defueled, an outage equipment hatch may be installed to allow access to containment. The outage equipment hatch is designed to provide a fission product barrier in the event of a design basis fuel handling accident and provides the same level of protection as the permanent inner equipment hatch in Mode 5, 6, or defueled. The outage equipment hatch will not replace the permanent inner equipment hatch during reduced inventory operation.

  Pipe Penetrations

  Other smaller penetrations through the containment include the MS and feedwater lines, hot and cold pipes, the fuel transfer tube, and electrical conductors. All penetration sleeves are welded to the liner and anchored into the reinforced concrete containment wall.

  Fuel Transfer Tube Penetration

  A fuel transfer tube penetration is provided for fuel transfer between the refueling canal in the containment structure and the SFP in the FB. The penetration consists of a 20-in stainless steel pipe inside a carbon steel sleeve. The inner pipe acts as the transfer tube; the outer tube is welded to the containment liner. The bellows expansion joints are provided to permit differential movement. The fuel transfer tube is equipped with a bolted blind flange with a double O-ring seal inside the containment.

  Electrical Penetrations

  Header plate-type penetrations are used for electrical conductors passing through the containment. The penetration header plate with double O-ring gaskets is bolted to a weld neck flange which is welded to a steel penetration sleeve. The steel penetration sleeves are welded to the containment vessel liner.

Containment Alternate Access for the SGs and Reactor Pressure Vessel Head (RVH) Replacement (Unit 1)

The SG and RVH Replacement Project created and restored a construction alternate access in the Unit 1 RCB (Containment Alternate Access) in accordance with administrative procedures and the design control program. The alternate access was used to facilitate movement of the original and replacement SGs and RVH out of and into the RCB. In accordance with the ASME Section XI repair/replacement program, the alternate access was restored consistent with the original containment specifications with any exceptions reconciled to the original specification.

The cut section of the RCB liner plate was rewelded to the liner plate with a full penetration weld. The new liner plate seam welds were examined using NDE methods specified within CC-5520. The liner weld was leak tested by vacuum box test method to satisfy leak-tightness requirements of NRC RG 1.19.

- Primary Shield Wall (PSW)

  The PSW, a heavily reinforced concrete cylinder, is situated at the approximate center of the Containment vessel and extends up from the interior base slab to surround the RV. This reactor cavity structure (cylindrical PSW) provides support for the RV. The vessel supports consist of support pads and shoes which are mounted on support members within the concrete cavity structure (PSW). During normal operation, the PSW provides biological shielding for maintenance inspection. Under seismic loading, this structure serves to provide seismic shear resistance and stiffens the Containment internal structure.

- Primary Loop Compartment Walls (SG Compartment)

  The compartments are formed by the secondary shielding walls on the exterior and by the reactor and refueling canal walls on the interior. These walls extend from the interior base slab up to the operating floor. The compartment houses the SG, RCPs, and the RCLs. The compartment walls provide radiation shielding, isolation of the RCS, and lateral restraint for the SGs, RCPs, and pressurizer.

- Refueling Cavity

  The refueling cavity (canal) provides shielded access for transport of spent fuel and new fuel between the RV and the fuel transfer penetration. It also provides shielding storage space for the RV internals during refueling or maintenance. The cavity is lined with stainless steel.

- Interior Base Slab

  The interior base slab is placed on top of the foundation mat liner plate and is 30-in thick. This slab provides lateral and flexural restraint at the base of the primary loop compartment walls and the PSW. The slab ties the primary loop compartment walls to the PSWs and provides a diaphragm for seismic shear distribution at the bottom of the internal structure. It also protects the foundation mat liner from any missiles generated in the primary loop compartments and from the effects of accident temperatures.

- Operating Floor

  The operating floor is supported by the primary loop compartment walls and concrete columns adjacent to the containment shell which extend down to the interior base slab. The operating floor provides a working and access floor during refueling, maintenance, and repair operations. Vent areas are provided where required.

- Intermediate Floors

  Intermediate floors are provided at several elevations, including a principal floor at EL. 860-ft for miscellaneous equipment supports, access, maintenance, and similar items.

- Recirculation Sumps and Screens

  Two sumps in the containment basement are provided. The sumps are physically separated and are located at the lowest elevation of the RCB exclusive of the RV cavity. Sump covers are provided to protect the sumps against falling debris. Stainless steel strainers are provided to preclude clogging of the recirculation lines and any of the system components.

<u>Boundary</u>

The internal structural components are:

- Associated with the leak tightness of containment; or
- Associated with the integrity of the RCB structure, including interior floors and columns; or
- Unique to the structure (e.g., the PSW, primary loop compartment (secondary shield) walls, and fuel transfer components); or
- Support major RCS components (i.e., RCPs, pressurizer, RV, SGs).

The LR boundaries for this structure are reflected on the LRBD below.

- LR-STRUCT-01

<u>Intended Functions</u>

The RCBs perform the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides primary containment boundary.

(2) Isolates the RCS from postulated environmental conditions including normal wind, tornados, and external tornado generated missiles.

(3) Provides support for the containment liner and penetrations, and nuclear safety related components.

(4) Contains the effects of the full range of postulated accidents, including LOCA, HELB, etc.

(5) Serves as shielding barriers for components and equipment from jet impingement and other postulated missiles.

(6) Provides a vapor barrier that will limit leakage from the containment following a LOCA within the containment.

(7) Provides a source of water for emergency core cooling during the recirculation phase.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs which could potentially affect the satisfactory accomplishment of nuclear safety related functions.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for EQ (10 CFR 50.49).

(3) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for PTS (10 CFR 50.61).

(4) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for ATWS (10 CFR 50.62).

(5) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

Recirculation sump	Direct flow
Recirculation sump cover	Shelter, protection
Recirculation sump effluent guard pipe	Shelter, protection
Recirculation sump liner	Pressure boundary Structural support
Service level I coatings	Maintain adhesion
Sliding surfaces	Structural support
Thermal insulation (high temperature penetrations)	Insulate

2.4.2. Auxiliary Building

Description

The AB is a Seismic Category I structure. The AB is a common building to both Unit 1 and Unit 2. The AB is a multistory, reinforced concrete structure with one story below grade and four stories above grade located between Unit 1 and Unit 2 containments and is approximately 120-ft by 192-ft. The building is divided into two parts, the auxiliary portion, and the electric portion, and they are interconnected. Adequate space is provided between the AB and adjacent structures to avoid the contact of structures, and systems are also designed to accommodate the differential movements of adjacent buildings.

The top of the AB foundation is at El. 790-ft 6-in with portions at El. 785-ft 6-in and is supported directly on bedrock. The slab at El. 900-ft 3-in serves as the roof for the AB. The floor at El. 852-ft 6-in has various floor openings provided with removable concrete slabs/hatches.

Interior and exterior tornado pressure relief dampers and exterior pressure relief blowout panels are installed in the AB. Tornado dampers are parallel multi-blade dampers and are normally closed. These dampers are designed to open in either direction when the differential pressure across the dampers reaches its setpoint.

The electric portion of the AB is referred to as the ECB and is separated from the AB proper by interior walls and doors.

Boundary

The AB structure is highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The AB is a Seismic Category I structure that houses ventilating equipment, waste treatment equipment, and other fluid auxiliary systems. Therefore, the AB performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for EQ (10 CFR 50.49).

(3) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.3. Diesel Generator Buildings

Description

CPNPP has two Seismic Category I DGBs, which are part of the SGBs. One building contains two DGs for Unit 1, and the second building contains two DGs for Unit 2. The separation between redundant DGs within each building is accomplished by locating each DG in a separate room partitioned by a concrete wall designed to withstand a safe shutdown earthquake (SSE), fire, or missiles. Each DG and its associated starting equipment and auxiliaries are located in the same room. Each DG is provided with independent room ventilation air intake and independent air discharge and engine inlet and exhaust ducts. The DGB for Unit 2 is on the North side adjacent to the Unit 2 SGB, and the DGB for Unit 1 is on the South side adjacent to the Unit 1 SGB. The mat slab foundation for each DGB is at El. 810-ft 6-in and is supported directly on bedrock. The DGB for each unit shares a common wall with the SGB and the other three walls are external walls. Openings in the external walls of the DGBs (e.g., for intake/exhaust) are protected from tornado generated missiles by a box-like structure made of concrete walls 2-ft 6-in thick and a 1-ft 9-in slab.

Boundary

The DGB structures are highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The DGBs are Seismic Category I structures that provide protection and shelter to the DGs. In addition, the DGs and auxiliary systems shall remain functional and withstand the effects of a PMF. Exhausts and vents of fuel oil and lube oil systems are located outdoors and designed such that seismic events and missiles cannot compromise the DGs nuclear safety related function. Failure of non-seismic structures or components shall not affect the function of the DG. Therefore, the DGBs perform the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.4. Electrical and Control Building

Description

The ECB is a Seismic Category I structure designed to resist the effects of a design basis tornado. The ECB is a multistory reinforced concrete structure common to both Unit 1 and Unit 2. The ECB is located between the AB and TB with an approximate plan area of 118-ft by 165-ft. The ECB foundation top is at El. 778-ft and is supported directly on bedrock. The slab at El. 873-ft 4-in serves as the roof slab for the ECB.

The Control Room, for both Units 1 and 2, is located in the ECB at El. 830-ft. The Control Room contains electrical panels/cabinets necessary for safe operation of the plant. Safe occupancy of the Control Room during abnormal conditions is provided for in the design. Adequate shielding is provided for the Control Room in the event of a DBA.

Interior and exterior tornado pressure relief dampers and exterior pressure relief blowout panels are installed in the ECB. Tornado dampers are parallel multi-blade dampers and are normally closed. These dampers are designed to open in either direction when the differential pressure across the dampers reaches its setpoint.

Boundary

The ECB structure is highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The ECB is a Seismic Category I structure. Control Room design is based upon the safe occupation of the CRE during normal operation and for a period of not less than 30 days after a LOCA. Therefore, the ECB performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

(2) Provides a centralized area for I&C necessary for safe plant shutdown.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for EQ (10 CFR 50.49).

(3) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for ATWS (10 CFR 50.62).

(4) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.5. Fuel Building

Description

The FB is a reinforced concrete structure whose principal function is to house the new fuel storage area and the two spent fuel storage pools. Both units are serviced by the common FB. The FB is a Seismic Category I structure and is designed to resist the effects of a design basis tornado. The FB is located between the Unit 1 and Unit 2 containment structures and its plan dimensions are approximately 143-ft 6-in by 137-ft 9-in. The bottom of the mat elevation varies with the lowest point at El. 780-ft 6-in and is supported directly on bedrock. The Service Water tunnel is part of the FB foundation and can be accessed from the lower floor of the AB El. 790-ft 6-in.

The FB has an overhead electric crane capable of handling the fuel shipping cask and a fuel handling crane which is mounted on the operating floor to transport new and spent fuel assemblies.

Two pools are provided for CPNPP spent fuel storage. Spent fuel assemblies and irradiated control rods are stored underwater in racks after transfer from the reactor. The fuel assemblies and control rods are held vertically in the racks located on the floor of the spent fuel storage pools. The two reinforced concrete pools are stainless steel lined and are an integral part of the FB.

New fuel assemblies and control rods are stored in a reinforced concrete pit located in the FB. The cask pit, an integral part of the FB, is provided for temporary dry storage and is equipped with storage racks of sufficient capacity for approximately one-third of the core for each unit. All surfaces that come into contact with the fuel assemblies are made of annealed austenitic stainless steel.

The refueling cavities inside the RCB, the SFPs, and the cask pit are all connected with a common transfer canal. Each connection between the transfer canal and the SFPs can be closed by gates. The SFPs, transfer canal, and cask pit are lined with stainless steel plates.

In preparation for refueling, the individual fuel assemblies are transported from the new fuel storage racks to the new fuel elevator using the fuel handling bridge crane or the FB overhead crane equipped with the new fuel handling tool. When an assembly has been lowered by the elevator, the fuel handling bridge crane equipped with the spent fuel handling tool can be used to place it either in the SFP for interim storage or in the Fuel Transfer System fuel basket for immediate transport into the containment.

Boundary

The FB structure is highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The principal function of the FB is to house the new fuel storage area and the two SFPs. The FB is a Seismic Category I structure. The pools, wet cask pit, and transfer canal sections are divided into separate and isolable areas by refueling gates. Therefore, the FB performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

(2) Controls the potential release of fission products to the external environment so that offsite consequences of DBEs are within acceptable limits.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for EQ (10 CFR 50.49).

2.4.6. Safeguards Buildings

Description

The SGBs are Seismic Category I structures and are designed to resist the effects of the design basis tornado. Each Unit at CPNPP has its own SGB and is approximately 62-ft 6-in by 98-ft including the DG area. All Seismic Category I structures, including the SGBs are founded on rock.

The SGB (for each unit) is a multistory, reinforced concrete structure. There are two stories below grade and four stories above grade. Adequate space is provided between the SGB and adjacent structures to avoid the contact of structures during SSE-induced motions. Piping and other systems crossing from the SGB and ECB to other buildings or structures are designed with sufficient flexibility to maintain their function within applicable code allowable stress limits during the SSE.

The floors below grade house the SI pumps, RHR pumps and coolers, containment spray pumps and coolers, and the auxiliary feedwater pumps. Floors above grade house the emergency DGs, electrical switchgear, MCCs, and CRDM controls.

Interior and exterior tornado pressure relief dampers and exterior pressure relief blowout panels are installed in the SGBs. Tornado dampers are parallel multi-blade dampers and are normally closed. These dampers are designed to open in either direction when the differential pressure across the dampers reaches its setpoint.

Boundary

The SGB structures are reflected on the LRBD below.

- LR-STRUCT-01

Intended Functions

The SGBs perform the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

(2) Controls the potential release of fission products to the external environment so that offsite consequences of DBEs are within acceptable limits.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for EQ (10 CFR 50.49).

(3) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.7. Safe Shutdown Impoundment and Dam

Description

A portion of the arm of the SCR formed by the channel of Panther Branch is utilized as a SSI, which holds water for normal and emergency cooling use. The secondary reservoir is separated from the main body of the reservoir by a rock-fill dam. The SSI Dam is designed and constructed to withstand the most severe postulated natural phenomena. An open spillway channel was excavated through the narrow ridge to the southwest of the SSI Dam, to connect the SSI with the main body of the reservoir. The floor of the channel is at El. 769-ft 6-in, six inches below the normal minimum operating level, such that water will pass back and forth to keep the large and small reservoir surfaces at the same elevation under normal operating conditions.

The SSI is designed to serve as the UHS of the CPNPP and acts to dissipate heat rejected by the SSW during post-accident shutdown and normal cooldown conditions. It has been sized to provide adequate cooling capacity in accordance with the requirements of NRC RG 1.27.

Boundary

The SSI Dam is highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The SSI is an enclosed body of water that is retained by the SSI Dam and serves as the UHS. The function of the UHS is to dissipate heat rejected from the SSW during normal conditions and DBEs. The SSI contains a water supply for a minimum of 30 days of reactor decay heat removal, without outside makeup. During low water levels in the SCR, the SSI is maintained at or above El. 769-ft 6-in by the safe shutdown dam and connecting canal. In addition, the FP makeup is from the SSI. Therefore, the SSI and Dam perform the following LR intended functions.

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides the UHS to dissipate heat rejected from the SSW during post-accident shutdown and normal cooldown conditions.

(2) Provides water to nuclear safety related SSCs for long-term use.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides water to SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

2.4.8. Service Water Intake Structure

Description

The SWIS is a Seismic Category I, reinforced concrete building located on the SSI. The structure foundation is at El. 749-ft with the top of slab at El. 755-ft. The operating deck of the structure is at El. 796-ft with the pump discharge centerline at

El. 800-ft. Access to the SWIS is provided by a personnel door and truck bay entrance at El. 810-ft 6-in.

The SWIS is socketed into rock with soil backfill on three sides above the top of the rock. The SWIS is protected from the effects of wind-wave activity on the SCR by the SSI and Dam.

Cooling water is returned to the SSI. Water from this structure enters the SSI at a point remote enough from the SWIS and at a velocity high enough to ensure adequate mixing, dispersion, and evaporative cooling of the effluent.

The SWIS provides housing to the nuclear safety related service water pumps and a NNS fire pump and is equipped with trash racks, traveling screens, stop gates, and screen wash pumps. Seismic Category I equipment, systems, and components in the SWIS are located above the PMF level and do not require protection from flood. Traveling screens perform their function with moving parts, are “active” and are not subject to AMR.

Boundary

The SWIS is highlighted on the LRBD below:

- LR-STRUCT-01

Intended Functions

The SWIS is designed to Seismic Category I requirements and all Category I structures are designed to withstand the effects of natural phenomena, such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The SWIS draws water from the SSI and supplies all nuclear safety related cooling systems. The nuclear safety related service water traveling screens provide long-term protection from the accumulation of debris and short-term protection against floating debris. Therefore, the SWIS performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.9. Switchgear Buildings

Description

The Switchgear Building for each unit are non-Category I buildings located between the TB and SGB for each unit and adjacent to the ECB. The Switchgear Buildings are designed to withstand a seismic event equal to the SSE. The Switchgear Buildings are provided with a reinforced concrete mat foundation with a maximum slab thickness of 6-ft and 3-ft 10-in at other locations. The mat slabs are founded on firm rock. They are independent and not connected to any other building structure. Adequate space is provided between each Switchgear Building and adjacent structures to avoid the contact of structures during an SSE event. The MS/FW lines running outside the SGB are supported on the roof of the Switchgear Buildings. NNS portions of the offsite power system (bus duct) are located in these buildings.

Boundary

The switchgear buildings are highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The Switchgear Buildings house components relied upon in the safety analyses and plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for ATWS and SBO. High-energy MS and Feedwater lines running outside the SGB, whose failure could impact nuclear safety related structures, are supported on the roof of the Switchgear Buildings. NNS portions of the offsite power system (bus duct) are located in these buildings. Therefore, the Switchgear Buildings perform the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulations for ATWS (10 CFR 50.62).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for SBO (10 CFR 50.63).

2.4.10. Turbine Buildings

Description

The TB for each unit is a non-Category I structure located adjacent to the AB. The TB is approximately 280-ft by 201-ft 9-in. The TB structures do not share a common mat with the adjacent Seismic Category I structure, and all structures are founded on firm rock. Sufficient space is provided between the TB and the adjacent category I structure to prevent contact because of deformations occurring in the structures during a seismic event. The TB is a multi-story reinforced concrete and steel-framed structure that has a steel superstructure with a metal siding enclosure above the turbine operating deck at El. 732-ft. Foundations for the turbine generators are within the TB but are structurally isolated.

The TB houses equipment associated with the main turbine generator. As the TB is a non-Category I structure and not designed for tornado loadings, the metal siding panels may fail at loads below the design tornado loading. The Seismic Category I structures are designed for the effects of tornado generated missiles.

The possibility of structural failure during a seismic event is considered for the TB. Structural failure in the direction of the adjacent Seismic Category I structure is prevented by the bearing of the mezzanine and operating floor slabs on the concrete turbine generator pedestal.

The TB complex houses various steam and power conversion (S&PC) equipment e.g., the main condenser, the moisture separator tanks, the condensate pumps, the heater drain pumps, the main turbines, the main generators, and various auxiliary systems.

Boundary

The TB structures are highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The TB complex is in scope for LR because several Seismic Category II high energy piping segments are located within the TB and are attached to adjacent Seismic Category I structures. These include portions of the SG blowdown lines and heater drain lines. The TB consists of one fire area (TB), divided into fire zones and subzones. Fire Area (TB) extends from EL. 775-ft 4-in to the roof of the TB. This fire area includes both the Unit 1 side and the Unit 2 side of the TB. The TB also houses NNS portions of the offsite power system. Therefore, the TB performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63).

2.4.11. Yard Structures

Description

The Yard Structures includes various concrete and steel buildings and structures in the scope of LR that are spread around the protected area, below and above grade. These include protective features associated with startup and alternate startup transformers, each unit's FWST foundation, firewater valve and pump houses, transformer foundations, duct banks, manholes and handholes, fuel oil storage tank slabs, and missile-protected Seismic Category I Tanks with the associated tunnels (that also cover the piping connections to the tanks). Detailed descriptions for the various yard structures are provided below.

Fire Barrier Walls/Enclosure Pits

The main transformers, unit auxiliary, and startup/alternate startup transformers are oil-cooled and are located outdoors adjacent to the TB. The main transformers are separated from each other, as well as from the TB, by a three-hour rated fire wall. The unit auxiliary transformers, startup transformers and one alternate (spare) startup transformer are separated from the TB by a three-hour rated fire wall. Penetrations in these walls within 50’-0” from each side of the center line of the transformer are protected, by seals or closures having a fire resistance rating equal to the rating assigned to the barrier, to maintain the fire-resistant integrity of the wall. Additional walls are provided extending out from the TB wall to protect the ventilation openings located in the exterior TB wall. The main, unit auxiliary, startup and one spare startup transformers are also surrounded by reinforced concrete enclosures/pits to contain oil spills and prevent the spread of fire.

FWST Foundations

The FWSTs, which are addressed in Section 2.3.3.7 are located on the east side of the FB and are provided to supply water to the Fire Protection Water Supply System. The tanks are provided with a reinforced concrete ring wall type foundation below the tank walls.

Firewater Pumphouse

The fire water pump house is common to both units and is a non-seismic building located on the east side of the FB. The fire water pumphouse is a single story block masonry structure. The building is provided with slab-on-grade reinforced with welded wire fabric (WWF) and a continuous footing for the 12-in thick masonry wall.

The pumphouse consists of five individual rooms which provides housing to the fire pumps, controllers, fuel tanks, and associated equipment located in separate rooms. The walls and seals for openings on the block wall of the fire water pumphouse are approved for a three-hour rated fire. The roof of the fire water pumphouse is a reinforced concrete slab 5.5-in thick on a 3-in metal deck supported by steel beams resting on the masonry wall at both ends. The roof slab is provided with 1-in insulation and built-up roofing protection. The firewater pumphouse is provided with an 8-in thick masonry wall as parapet with precast coping on the top.

Firewater Valve Houses

The Firewater Valve Houses are small metal building structures approximately 10-ft by 10-ft in size installed over a slab-on-grade foundation and provide shelter to the Fire Suppression System.

FOST Slabs

At CPNPP, each Unit is supplied with two full-sized DG sets which are supported by an independent FOSTS train. Each train consists of a buried FOST designed as Seismic Category I. A concrete slab-on-grade is provided as the tornado missile protection for the storage tanks and associated piping. A below-grade foundation slab is designed to provide support for the FOSTs, which are addressed in Section 2.3.3.5.

Manholes, Handholes, Duct Banks

Manholes and handholes consist of reinforced concrete rectangular box structures buried underground with a steel cover. There are nuclear safety related and NNS manholes located in the yard area. Nuclear safety related manholes are provided with a steel plate over the standard manhole cover for missile protection. Handholes are similar to manholes but smaller in size and provided at intersections of duct banks for the ease of cable installation.

Class IE cables are routed between non-adjacent Seismic Category I buildings via Category I duct banks. The duct banks consist of rigid metal conduits encased in concrete resting on bedding and backfill materials. Duct bank rigid conduit ends and building rigid conduit ends are connected by means of flexible metal conduits. Both ends of the flexible conduits are provided with liquid tight and threaded connectors.

Outdoor Seismic Category I Tanks – RWST, CST, RMWST and Associated Piping Tunnels

All Seismic Category I Tanks contain fluid which feed nuclear safety related piping systems such as the AFW and SI Systems. Reinforced concrete tanks are circular in shape, with stainless steel liners to provide leak tightness. For the RWST, the liner also prevents absorption of radioactive material by the concrete structure. Seismic Category I tanks are also designed to resist the effects of the design basis tornado. The RWST, CST and the RMWST for Unit 2 are located on the north side of the plant next to the DGB attached to the SGB. The RWST, CST and the RMWST for Unit 1 are located on the south side of the plant.

The tanks are designed to withstand all credible loadings and to maintain their integrity during operation. These loadings include both normal operating loads such as structure weight, hydrostatic pressure of the contained fluid, live loads on the roof, thermal loads, and environmental loads such as the 1/2 SSE, SSE, normal wind, and tornados (wind, differential pressure, and missiles), and hydrodynamic forces caused by seismic effects on the contained fluid.

These nuclear safety related tanks are also addressed in Sections 2.3.2.3, 2.3.4.1, and 2.3.3.4, respectively, relative to the contained fluid.

A tunnel is provided for each unit which runs between the outdoor Seismic Category I tanks and the SGB for the respective unit. The Seismic Category I pipe tunnel structures protect nuclear safety related piping systems against damage from environmental effects, including the effects of the design basis tornado. At each tank location the tunnel structure extends above ground to EL. 824-ft 6-in and provides access to these tunnels. The tunnel structure is independent of the tank structure and is separated by an expansion joint.

Transformer Foundations

The startup transformers and alternate startup transformer support SBO recovery. Reinforced concrete foundation pads are provided for startup transformers), and alternate startup transformers.

Boundary

Yard structures are highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The Yard Structures perform the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

Fire barrier walls/Enclosure pits

(1) None.

FWST foundations

(2) None.

Firewater Pumphouse

(3) None.

Firewater Valve Houses

(4) None.

FOST slabs

(5) Provides physical support, shelter, and protection for nuclear safety related SSCs.

Manholes, Handholes, Duct Banks

(6) Provides physical support, shelter, and protection for nuclear safety related SSCs.

Outdoor Seismic Category I Tanks –RWST, CST, RMWT and Associated Piping Tunnels

(7) Provides physical support, shelter, and protection for nuclear safety related SSCs.

Transformer Foundations

(8) None.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

Fire barrier walls/Enclosure pits

(1) None.

FWST foundations

(2) None.

Firewater Pumphouse

(3) None.

Firewater Valve Houses

(4) None

FOST slabs

(5) None.

Manholes, Handholes, Duct Banks

(6) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

Outdoor Seismic Category I Tanks –RWST, CST, RMWT and Associated Piping Tunnels

(7) Provides physical support, shelter, and protection for NNS SSCs whose failure could prevent the satisfactory accomplishment of function(s) identified for 10 CFR 54.4(a)(1).

Transformer Foundations

(8) None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

Fire barrier walls/Enclosure pits

(1) Provides physical support, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48).

FWST foundations

(2) Provides physical support, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48).

Firewater Pumphouse

(3) Provides physical support, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for FP (10 CFR 50.48).

Firewater Valve Houses

(4) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

FOST slabs

(5) None.

Manholes, Handholes, Duct Banks

(6) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

Outdoor Seismic Category I Tanks –RWST, CST, RMWT and Associated Piping Tunnels

(7) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(8) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for EQ (10 CFR 50.49).

(9) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for SBO (10 CFR 50.63).

Transformer Foundations

(10) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

2.4.12. Switchyard Structures

Description

The CPNPP switchyards are located approximately 600-ft due west of the TB. The 345 kV CPNPP Control House (houses the batteries needed for the SBO 345 kV Switchyard breakers) and the 138 kV Relay House (houses the batteries needed for the SBO 138 kV switchyard breakers) are metal buildings supported by structural steel framing members. The relay houses are single story structures provided with isolated footings for the column members and a slab-on-grade type floor. Internal cable trenches with checkered cover plates are provided to route the cables inside the relay house.

Reinforced concrete foundations are provided for the various six-pole, two-pole, and single-pole structures supporting switchyard electrical apparatus. Precast concrete cable trenches and precast lids are used throughout the switchyard to run the underground cables.

Boundary

The switchyard structures are highlighted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The Switchyard Structures perform the following LR intended function:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission’s regulation for SBO (10 CFR 50.63). 10 CFR 54.4(a)(3)

2.4.13. Component Support Commodity Group

Description

The component support commodities located within the structures that are in scope for LR include:

- Anchorage/embedment

  Components that facilitate structural attachment to concrete such as grouted-in and through-bolts, cast-in-place anchor bolts, expansion anchors, Richmond inserts, headed studs, base plates, anchor plates, corner angles and miscellaneous bolts and nuts are considered to be anchorage/embedment components within the scope of LR. In-scope bolting also includes (non-containment) liner anchors and penetration anchors.

- Bird screen

  Pest control screens that support ventilation systems to prevent pests such as birds and rodents from entering/interfering with ventilation system functions. Bird screens are attached to air intakes, louvers, and vents and are within the scope of LR.

- Bolting (structural)

  Bolting supporting the intended function of a component, ductwork, and piping support or a structural bulk commodity such as cable trays, conduits or bolting for connections associated with structural steel assemblies such as decking, grating, handrails, ladders, platforms, stairs, vents, and louvers, are within the scope of LR. Structural bolting not included as part of this commodity are:

- Containment closure bolting (associated with the containment liner or penetrations) listed in Section 2.4.1 above,
- Structural bolting associated with building structures such as connections for main beams, columns and other structural frames listed in Sections 2.4.2 to 2.4.12 above, and
- Structural bolting associated with crane members and connections, “hardware”, listed in Section 2.4.14 below.

- Cabinet, panel, rack, and other enclosure

  Electrical and instrumentation enclosures for in-scope cabinets, junction boxes, instrument panels and racks and other electrical equipment are within the scope of LR.

- Cable tray

  Cable trays, and associated hangers, clamps, tray fittings, splices and other cable tray components that provide structural support and shelter/protection for various EIC system cables in the scope of LR are within the scope of LR.

- Conduit

  Conduit systems provide the means of conveying electrical cables to and from termination points at equipment and other electrical raceways (cable trays) in a manner that assures that the cable is protected from mechanical and electrical damage. Conduit systems include rigid conduits, flexible conduits, conduit supports, and conduit fittings such as couplers and unions and are within the scope of LR.

- Door

  Doors/hatches include components that act as structural pressure barriers, radiation shields, flood barriers, and missile resisting doors. Doors/hatches also include other miscellaneous doors such as hollow metal doors, and aluminum doors that separate different areas of the building(s). Fire barrier doors that perform an intended function for FP are addressed as a different commodity group (Section 2.4.15). Watertight doors, hatches, hatch covers, missile barriers, and other miscellaneous doors are limited to certain structures and are addressed with those structures in Sections 2.4.2 to 2.4.12 above. Likewise, containment airlocks and equipment hatches are addressed with that structure in Section 2.4.1 above.

- Equipment foundation pad/pedestal

  The equipment foundation pads/pedestals anchor and support equipment/ components above the floor/grade elevation. Equipment foundation pads/pedestals that support components/equipment within the scope of LR are within the scope of LR.

- Insulation

  Insulation includes insulating cement, thermal insulation, anti-sweat insulation, anti-freeze insulation, heat tracing, and reflective metal insulation. Plastic insulating cement may be used on surfaces operating at a temperature between 100°F and 1000°F. Reflective insulation is not critical to the safety of the plant; however, should any of the component parts of the reflective insulation be dislodged during a design basis earthquake, the operation of critical piping and equipment could be impaired. The reflective insulation assemblies were, therefore, installed to Seismic Category II requirements. Piping and equipment operating at temperatures lower than the dew point of surrounding ambient conditions are provided with anti-sweat insulation. Conservatively, outdoor piping is equipped with insulation for anti-freeze protection. Additionally, certain piping and equipment in select rooms of the SGB and AB require ESF thermal insulation. Except for the piping and equipment in select rooms of the SGB and AB which require ESF thermal insulation, for post-accident operation and anti-sweat/anti-freeze insulation described above, other insulation is for personnel protection rather than for process requirements. Furthermore, insulation is removed from insulated piping that goes through a sealed penetration or sleeve (such as associated with the CRE or pressurization requirements for the Auxiliary, Fuel and SGBs) and there is a minimum clearance between insulation and an unsealed penetration or sleeve. Insulation associated with containment penetrations and PSW tunnels are addressed separately with that structure in Section 2.4.1 above.

- Insulation jacketing

  Insulation jacketing consists of the jacketing/vapor barrier for all insulated plant piping and equipment that are in the scope of LR and includes the associated straps, tie wires and clips.

- Louver and damper

  Louvers and dampers are devices that are used to regulate the flow of air in a structure. Louvers and damper housings that perform a LR intended function of shelter and protection and are located in structures within the scope of LR are included in the scope of LR.

- Miscellaneous steel (e.g., stair, catwalk, handrail, decking, grating, ladder, framing and platform)

  Miscellaneous components such as stairs, catwalks, handrails, decking, grating, ladders, framing, and platforms located within nuclear safety related structures and whose failure during a DBE can cause an impact or spatial interaction concern with nuclear safety related SSCs, are within the scope of LR.

- Moment restraint

  Moment restraints are provided to protect the containment isolation valves, process pipes and penetrations within the break exclusion areas (BEAs) for HELBs. The moment restraints include forgings that are part of the pressure boundary and are addressed in Sections 2.3.1.3, 2.3.3.1, 2.3.4.1, 2.3.4.2, and 2.3.4.3.

- Penetration seal

  Penetration seals within the scope of LR include material seals used for mechanical and electrical penetrations in (non-containment) walls, floors and ceilings that are designed to provide structural support, maintain the structural pressure barrier and act as a flood, radiation, and HELB shielding. Fire barrier penetration seals are included in the Fire barrier commodity group.

- Penetration sleeve

  Penetration sleeves provide a means for supporting and sealing mechanical and electrical penetrations through walls, floors, and other barriers outside of containment. Penetration sleeves are typically provided for openings through barriers for pipe, conduit, instrumentation, bus ducts, HVAC ducts, and cable trays. Seals provide pressure, radiation, fire barrier and environmental integrity.

- Pipe whip restraint and jet impingement shield

  Pipe whip restraints and jet impingement shields are support structures that function to limit the movement of a ruptured pipe and hence protect essential components within the scope of LR from pipe whip and/or jet impingement effects. The pipe whip restraints used by CPNPP are U-bar, crushable pipe (bumper), crushable pad (honeycomb), and elastic restraints. The elastic restraints are moment restraints, hard restraints and pipe supports.

- Roofing membrane

  Roofing membranes in the scope of LR consist of the roofing membranes that perform the LR intended function of providing shelter/protection for structures within the scope of LR. This component type only includes the roofing membranes and does not include the associated structural framing/supports for roofs. Structural components that support the roofs are identified and evaluated with the associated structures.

- Seal, gasket, and moisture barrier (caulking, flashing and other sealant)

  Caulking, flashing, and other sealants used to seal building wall joints, perimeter joints of door frames, windows, louvers, and other opening frames in contact with concrete or masonry construction, interior floor, roof, and wall joints. Caulking, flashing, and sealants used on structures within the scope of LR are within the scope of LR.

- Support bolting for ASME Class 1 piping, and Class 2 and 3 piping and components

  Bolting used for constant and variable load spring hangers; struts; snubbers; guides; and stops that support nuclear safety related components in the scope of LR are included in the scope of LR. Bolting for major RCS Class 1 components is listed in Section 2.4.1 above.

- Support for ASME Class 1, 2, and 3 piping and Class 2 and 3 piping and components

  These constant and variable load spring hangers; struts; snubbers; guides; and stops support nuclear safety related components in the scope of LR and are included in the scope of LR. Supports for ASME Class 1 major components (RV and CRDMs, pressurizer, RCPs and SGs) are not included in this commodity but are addressed in Section 2.4.1 above with the containment structure to which they are attached.

- Support member

  This component group includes support members, as well as hangers, for all other ductwork, piping, tubing, and components (that are not ASME Class 1, 2, or 3 piping and components), including electrical cabinet, rack, panel, enclosure, cable tray, and conduit within the scope of LR.

- Tube track

  Tube track within the scope of LR is associated with various instrumentation tubing that is within the scope of LR.

<u>Boundary</u>

The component support commodities are contained in the structures within scope of LR. These structures are depicted on the LRBD below.

- LR-STRUCT-01

Intended Functions

The Component Support Commodity group performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support, shelter, and protection for nuclear safety related SSCs that perform nuclear safety related intended functions.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support, shelter, and protection for NNS SSCs whose degradation and failure could impede or prevent a nuclear safety related SSC from accomplishing its intended function(s).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for EQ (10 CFR 50.49).

(2) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for ATWS (10 CFR 50.62).

(3) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for FP (10 CFR 50.48).

(4) Provides physical support, shelter, and protection for SSCs relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulation for SBO (10 CFR 50.63).

Component Support Commodity Group Subject to Aging Management Review

Commodity	Intended Function(s)
Support for ASME Class 1 (piping) and Class 2 and 3 piping and components	Structural support
Support member	Structural support
Tube track	Shelter, protection Structural support

[1] Thermal insulation of piping and equipment in select ESF rooms of the SGBs and AB (for the ESF area/room coolers to provide adequate cooling post-accident) and the antifreeze outdoor piping insulation (to keep boron in solution) is required.

[2] Component type does not include louver or damper housings credited with pressure relief for a Tornado, addressed in Tables 2.4-2, 2.4-3, 2.4-4 and 2.4-6, or fire damper housings, addressed in Table 2.4-15.

2.4.14. Crane/Hoist Commodity Group

Description

Cranes and hoists are used to safely move material and equipment supporting operations and maintenance activities and are designed to be in compliance with NUREG-0612. Cranes or hoists which handle a critical load which, if dropped, could prevent safe shutdown, or result in offsite radiation releases comparable to 10 CFR Part 100 limits are designed to prevent that load drop and are designated nuclear safety related and are within the scope of LR.

Additionally, overhead load handling systems (e.g., cranes, hoists, etc.) whose failure could result in damage to a nuclear safety related SSC that could prevent the accomplishment of a safety function are within the scope of LR based on the criterion of 10 CFR 54.4(a)(2).

Overhead load handling systems with the potential for heavy load drop on or near spent fuel or systems required for plant shutdown or decay heat removal are in the scope of LR.

The handling of heavy loads outside of structures by the use of non-permanent load handling systems are subject to engineering evaluation and work control review. Routine use of mobile cranes that have already been identified and evaluated include the removal of equipment from containment (e.g., RCP motors), from the SWIS (e.g., SSW pumps and motors), and between the FB and the ISFSI (e.g., DCSS HI-STORMs).

The following precautions are taken for such non-permanent load handling systems:

- When traversing very heavy loads (e.g., SSW pumps, SSW motors, RCP motors) in the yard, the load should not be carried over underground nuclear safety related facilities unless special precautions are taken to minimize risk.

- When traversing very heavy loads over underground nuclear safety related facilities (Diesel Fuel Oil Storage tanks, Service water Pipe Tunnels and buried piping, and Class 1E duct banks) in the yard, the load should be carried as low as practical.

- When traversing very heavy loads (e.g., SWIS roof hatches, pumps, or motors) over the SWIS, the load should be carried as low as practical and take the shortest route to a safe load area (i.e., not over underground nuclear safety related facilities).

Boundary

The cranes and hoists are contained in the structures that are within the scope of LR. These structures are depicted on the site LRBD.

- LR-STRUCT-01

Intended Functions

The Crane/Hoist Commodity Group performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) Provides physical support for nuclear safety related SSCs.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) Provides physical support for NNS SSCs whose degradation and failure could impede or prevent a nuclear safety related SSC from accomplishing its intended function(s).

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) None.

2.4.15. Fire Barrier Commodity Group

Description

Fire barriers are those components of construction (walls, floors, or protective covering) that are rated by approved laboratories or are constructed in accordance with the requirements stated by authorities having jurisdiction. Barriers are rated in hours of resistance to fire and are used to prevent the spread of fire. The integrity of a fire barrier may also be substantiated by either a fire test or an FHA (fire hazards analysis) evaluation. Similarly, a fire break is a physical barrier that prevents fire propagation, that is, the spreading of a fire from one component to another or direct exposure of a component to the heat and flames of a fire, or both.

Fire barriers are part of the plant FPS and perform an intended function and are included within the scope for LR per the Commission's regulations for FP (10 CFR 50.48). For LR considerations, fire breaks are considered as fire barriers.

Fire barriers and associated components within the scope of LR include:

- Cable raceway fire barriers

  Cable raceway fire barriers are used to isolate some cable raceways from local fire exposures. The fire barriers used on raceways have a one-hour or three-hour fire rating, as applicable.

- Concrete block (removable) for opening

  Removable concrete block openings are provided in certain walls to facilitate equipment removal and replacement. Thus, in areas where a removable concrete block opening exists in a fire wall, an FHA evaluation justifies the as-built design, and the concrete blocks are installed in such a way that there are no through openings from one side of the barrier to the other. The concrete blocks are also restrained in the openings so that they will remain in place during a fire or seismic condition.

- Damper

  HVAC ductwork which penetrates fire barriers is installed in accordance with NFPA-90A and an Underwriters Laboratory (UL) listed fire damper that has a rating at least commensurate with the barrier in which it is installed is provided in the duct.

- Door

  With the exception of watertight and missile- and bullet-resistant doors, the door openings in fire barriers are provided with approved fire doors which carry a fire rating at least equivalent to the rating of the barrier and comply with the guidance provided by UL or are validated by a fire test from a recognized testing laboratory.

  Primary design criteria for a watertight door is containment of internal flood water to prevent damage to redundant essential equipment and systems. The fire severity in the area for the door location is moderate, and the maximum permissible fire loading value is low to moderate. The fire detection and sprinkler system is relied upon for fire protection in the areas where watertight doors are provided.

  Primary design criteria for the missile- and bullet-resistant doors is resistance to externally generated missiles. The fire severity in the area for the door location is moderate, and the maximum permissible fire loading value is low. Automatic sprinkler suppression is provided where the potential for exposure of nuclear safety related systems exists. Ionization detection is provided throughout the area.

- Hatch

  Hatches are provided through floors in various locations to facilitate equipment removal and replacement. In areas where these hatches pass through a floor which serves as a fire barrier, the hatches are fire rated equal to or greater than that of the fire barrier.

- Insulation and wrap

  This component group includes insulation provided for piping and other components that are non-combustible or have been tested and qualified by UL. This commodity group also include fireproofing material used on cable trays and structural steel fireproofing such as Thermo-Lag and radiant energy shields (RESs).

- Penetration seal

  Penetration seals are used to seal openings through interior fire barriers for pipe, conduit, instrumentation, bus ducts, duct work, and cable trays. Seals provide a fire rating greater than or equal to the barriers in which they are installed except where justifications for deviations have been written.

- Penetration sleeve

  Penetration sleeves provide a means for supporting and sealing mechanical and electrical penetrations through walls, floors, and other barriers outside of

Containment. Penetration sleeves are typically provided for openings through barriers for pipe, conduit, instrumentation, bus ducts, HVAC ducts and cable trays. Seals provide pressure, radiation, fire barrier and environmental integrity.

- Wall, floor, and ceiling
  - Reinforced concrete fire walls, floors, and ceilings comply with either UL listed designs, the Uniform Building Code (UBC), or are a tested configuration.
  - Structural steel associated with the metal siding panels and the internal structure of the TB that are protected with a fire-resistant coating in areas where the steel members are adjacent to a fire barrier, are a part of a fire barrier, or are exposed to a potential fire hazard as identified in the Fire Hazards Analysis.
  - Structural steel supporting fire dampers, tornado vents, and fire barrier penetrations such as doors, vents, etc.
  - Unit masonry is utilized throughout the plant site, usually where reinforced concrete was not feasible. Unit masonry construction provides fire-resistant barriers separating one fire area from another.
  - Gypsum drywall is utilized throughout the plant to provide a fire barrier which is lightweight and where unit masonry or concrete is not feasible.
- FP hose station (including rack, reel, and support)

  Hose stations are located strategically throughout the plant for manual firefighting operation and are installed in nuclear safety related buildings such that an effective hose stream can reach any location in a nuclear safety related building.

Boundary

The fire barriers are contained in the structures that are within the scope of LR. These structures are depicted on the site layout LRBD.

- LR-STRUCT-01

Intended Functions

The Fire Barrier Commodity Group performs the following LR intended functions:

Nuclear safety related functions (10 CFR 54.4(a)(1)):

(1) None.

NNS that could affect nuclear safety related functions (10 CFR 54.4(a)(2)):

(1) None.

FP, EQ, PTS, ATWS, and SBO functions (10 CFR 54.4(a)(3)):

(1) Relied upon in safety analyses or plant evaluations to perform a function that demonstrates compliance with the Commission's regulations for regulated events for FP (10 CFR 50.48). That is, serve as a rated fire barrier or provide structural support for components used for manual firefighting.

Hatch	Fire barrier
Insulation and wrap	Fire barrier
Penetration seal	Fire barrier
Penetration sleeve	Fire barrier
Wall, floor, and ceiling	Fire barrier
FP hose station (rack, reel, and support)	Structural support

2.5. SCOPING AND SCREENING RESULTS: ELECTRICAL

The determination of EIC systems that fall within the scope of LR is made through the application of the process described in Section 2.1. The results of the electrical systems scoping review are contained in Section 2.2 and employ an in-scope bounding approach whereby all EIC systems are included in scope (unless noted otherwise). When used with the plant spaces approach, this encompassing or bounding approach eliminates the need for unique identification of each EIC component and its specific location. Intended functions for EIC systems are not identified since the bounding scoping approach makes it unnecessary to determine if an EIC system has an intended function. This assures components are not improperly excluded from AMR but does not prevent elimination of commodity groups or specific plant systems from AMR in accordance with the screening guidance of 10 CFR 54.21.

The methodology used in identifying EIC components requiring an AMR is discussed in Section 2.1.6.1. The screening for EIC components was performed on a generic component commodity group basis for all EIC systems listed in Table 2.2-1, as well as the EIC component commodity groups associated with mechanical systems and civil structures listed in Table 2.2-1. The methodology employed is consistent with the guidance in NEI 95-10.

The interface of EIC components with other types of components and the assessments of these interfacing components are provided in the appropriate mechanical or structural sections. For example, the assessment of electrical racks, panels, frames, cabinets, cable trays, conduits, and their supports is provided in the structural assessment documented in Sections 2.4 and 3.5.

The EIC components included in the screening are the separate EIC components that are not parts of a larger (active) component or assembly. For example, the wiring, terminal blocks, and connections located internal to a breaker cubicle are considered to be parts of the breaker. Accordingly, the breaker was screened, but the internal parts of the breaker were not screened.

2.5.1. Electrical and I&C Component Commodity Groups

2.5.1.1. Identification of Electrical and I&C Components

The EIC component commodity groups were identified from a review of electrical systems within the scope of 10 CFR Part 54, controlled electrical drawings, the MEL, and interface with the mechanical and structural screening process. This commodity based approach, whereby component types with similar design and/or functional characteristics are grouped together, is consistent with guidance from NEI 95-10 and Table 2.1-5 of NUREG-1800. The in-scope EIC component commodity groups identified at CPNPP Units 1 and 2 are listed in Table 2.5-1.

2.5.1.2. Application of Screening Criterion 10 CFR 54.21(a)(1)(i) to the Electrical and I&C Components and Commodities

Following the identification of the electrical components and commodity groups, the criterion of 10 CFR 54.21(a)(1)(i) is applied to identify EIC commodity groups that perform their functions without moving parts or without a change in configuration or properties. The following EIC commodity groups meet the screening criteria of 10 CFR 54.21(a)(1)(i) for CPNPP:

- Insulated cables and connections
- EIC penetration assemblies
- Metal enclosed bus
- High-voltage insulators
- Switchyard bus and connections
- Transmission conductors and connections
- Uninsulated ground conductors

2.5.1.3. Elimination of Electrical and I&C Commodity Groups Not Applicable to CPNPP

The following EIC commodity groups are not applicable to CPNPP:

Cable Tie-Wraps

At CPNPP, cable fasteners and tie-wraps are intended to be used for training cables, assembling wires or cables into neat bundles and for general housekeeping purposes. Cable fasteners and tie-wraps are not considered a cable support. Electrical cable tie-wraps do not function as cable supports in raceway support analyses; therefore, the installation and inspection criteria are limited to the application of standard practices in providing quality cable bundles and cable placement. The seismic qualification of cable trays does not credit the use of electrical cable tie-wraps. Cable tie-wraps do not have an LR intended function as defined in 10 CFR 54.4, therefore they are not subject to AMR.

Fuse Holders (Metallic Clamps)

The cables and connections commodity group includes fuse holders (fuse blocks). Consistent with NUREG-1801 XI.E5, NEI 95-10 Appendix B Item 77, NUREG-1800 Table 2.1-5 Item 77, and NUREG-1950 Table II-13, the screening of fuse holders (metallic clamps) applies to those that are not part of active equipment. This screening guidance is consistent with the original guidance provided to LR applicants under NRC letter dated March 10, 2003 through ISG-05 (Reference ML030690512). Fuse holders inside the enclosure of active equipment, such as switchgear, power supplies, power inverters, battery chargers, and circuit boards are considered piece parts of the active equipment. Since piece parts and subcomponents in such an enclosure are routinely inspected and regularly maintained as part of normal maintenance and surveillance activities, they are not subject to AMR (Reference 1.7.15).

To discover the population of fuse holders located outside of active equipment, a plant equipment database query was developed. Then, fuse locations were determined utilizing tag information and plant engineering expertise. The results of the equipment database evaluation confirmed there are no fuses which support a system intended function and are not part of an active equipment such as switchgear, power supplies, power inverters, battery chargers, load centers, and circuit boards. It is concluded that fuses, including metallic clamps for the fuse clips of the fuse holders, are considered piece parts of the active equipment and are therefore not subject to AMR.

2.5.1.4. Application of Screening Criteria 10 CFR 54.21(a)(1)(ii) to Electrical and I&C Commodity Groups

The 10 CFR 54.21(a)(1)(ii) screening criterion was applied to the specific commodities that remained following application of the 10 CFR 54.21(a)(1)(i) criterion. Criterion 10 CFR 54.21(a)(1)(ii) allows the exclusion of those commodities that are subject to replacement based on a qualified life or specified time period. The only electrical commodities identified for exclusion by the criteria of 10 CFR 54.21(a)(1)(ii) are EIC components and commodities included in the EQ Program (10 CFR 50.49). This is because EIC components and commodities included in the Environmental Qualification of Electric Components (B.2.2.2) AMP have defined qualified lives and are replaced prior to the expiration of their qualified lives. No EIC components and commodities within the Environmental Qualification of Electric Components (B.2.2.2) AMP are subject to AMR in accordance with the screening criterion of 10 CFR 54.21(a)(1)(ii). Note that TLAAs associated with EIC components within the Environmental Qualification of Electric Components (B.2.2.2) AMP are discussed in Section 4.4.

Insulated Cables and Connections

The function of insulated cables and connections is to electrically connect specified sections of an electrical circuit to deliver voltage, current, or signals. Electrical cables and their required terminations (i.e., connections) are reviewed as a single component commodity group. The types of connections included in this review are splices, connectors, and terminal blocks. Numerous insulated cables and connections are included in the Environmental Qualification of Electric Components (B.2.2.2) AMP. The insulated cables and connections that are included in this program have a qualified life that is documented in the Environmental Qualification of Electric Components (B.2.2.2) AMP. Components in the Environmental Qualification of Electric Components (B.2.2.2) AMP are replaced prior to the expiration of their qualified life. Accordingly, all insulated cables and connections within the Environmental Qualification of Electric Components (B.2.2.2) AMP are replacement items under 10 CFR 54.21(a)(1)(ii) and are not subject to AMR. Note that TLAAs associated with electrical/I&C components within the Environmental Qualification of Electric Components (B.2.2.2) AMP are discussed in Section 4.4.

Insulated cables and connections that perform an intended function within the scope of LR but are not included in the Environmental Qualification of Electric Components (B.2.2.2) AMP, meet the criterion of 10 CFR 54.21(a)(1)(ii) and are subject to AMR.

Switchyard Bus and Connections, High-voltage Insulators, Transmission Conductors and Connections

NUREG-1801, Chapter VI.A addresses components that are relied upon to meet the SBO requirements for restoration of offsite power. This guidance is consistent with the original guidance provided to LR applicants under NRC letter dated April 1, 2002 (Reference ML020920464). Consistent with this guidance, the switchyard commodities of switchyard bus and connections, high-voltage insulators, and transmission conductors and connections perform an intended function for restoration of offsite power following a SBO event. Additionally, none of these commodities are included in the Environmental Qualification of Electric Components

(B.2.2.2) AMP. Thus, these commodities meet the criterion of 10 CFR 54.21(a)(1)(ii) and are subject to AMR.

Figure 2.5-1 identifies the major components or commodities associated with restoration of off-site power following a SBO event.

Metal Enclosed Bus

Metal enclosed bus (MEB) is used to connect two or more elements (i.e., electrical equipment such as switchgear and transformers) of an electrical circuit. This commodity group includes three broad categories of MEB: isolated (iso) phase bus, non-segregated phase bus, and segregated phase bus. Iso-phase bus is electrical bus in which each phase conductor is enclosed by an individual metal housing separated from adjacent conductor housings by an air space. Non-segregated phase bus is electrical bus constructed with all phase conductors in a common enclosure without barriers (only air space) between the phases. Segregated phase bus is electrical bus constructed with all phase conductors in a common enclosure but segregated by metal barriers between phases. Segregated phase bus is not utilized at CPNPP, and the iso-phase bus does not perform or support an LR intended function. Only non-segregated phase MEB utilized in the restoration power path for offsite power following a SBO event performs an LR intended function, and this MEB is not in the Environmental Qualification of Electric Components (B.2.2.2) AMP. Therefore, non-segregated phase MEB used in the restoration of offsite power meets the criterion of 10 CFR 54.21(a)(1)(ii) and is subject to AMR.

Electrical and I&C Penetration Assemblies

All CPNPP EIC penetration assemblies are included in the Environmental Qualification of Electric Components (B.2.2.2) AMP (10 CFR 50.49). CPNPP EIC penetration assemblies included in the Environmental Qualification of Electric Components (B.2.2.2) AMP are subject to replacement based on their qualified life, therefore they are not subject to AMR. Non-EQ cables and connections to EIC penetrations are evaluated in the insulated cables and connections commodity group.

Uninsulated Ground Conductors and Connections

Uninsulated ground conductors and connections are used in lightning protection applications to protect CPNPP buildings and equipment from lightning strikes by providing a low resistance path to ground. No uninsulated ground conductors and connections are included in the EQ Program. Thus, this commodity group meets the criterion of 10 CFR 54.21(a)(1)(ii) and is subject to AMR.

2.5.2. Electrical and I&C Commodity Groups Subject to Aging Management Review

Table 2.5-2 lists the EIC commodity groups subject to AMR and their associated component intended functions.

3.0. AGING MANAGEMENT REVIEW RESULTS

This chapter provides the results of the AMR for those structures and components identified in Section 2.0 as being subject to AMR. Organization of this chapter is based on Tables 3.1-1 through 3.6-1 of NUREG-1801 Revision 2.

The major sections of this chapter are:

- Aging Management of Reactor Vessel, Internals, and Reactor Coolant System (Section 3.1)
- Aging Management of Engineered Safety Features (Section 3.2)
- Aging Management of Auxiliary Systems (Section 3.3)
- Aging Management of Steam and Power Conversion Systems (Section 3.4)
- Aging Management of Containments, Structures, and Component Supports (Section 3.5)
- Aging Management of Electrical and Instrumentation and Controls (Section 3.6)

Tables 3.0-1, 3.0-2, and 3.0-3 provide descriptions of the mechanical, structural, and electrical service environments, respectively, used in the AMRs to determine aging effects requiring management. The environments used in the AMRs are listed in the first column. The second column includes the definition for the environment and a description of any key relevant conditions, such as temperature in degrees Fahrenheit (°F), in that environment. The third column identifies one or more of the NUREG-1801 environments, as supplemented by LR-ISGs, that are used when comparing the CPNPP AMR results to the NUREG-1801 results. The definitions of those environments correspond to the definitions in NUREG-1801, Section IX.D.

Most of the AMR results information in Section 3 are presented in the following two tables:

Table 3.x-1 - where ‘3’ indicates the LRA section number, ‘x’ indicates the subsection number from NUREG-1801, and ‘1’ indicates that this is the first table type in Section 3. For example, in the Reactor Vessel, Internals, and Reactor Coolant System subsection, this table would be number 3.1-1, in the ESF subsection, this table would be 3.2-1, and so on. For ease of discussion, this Table will, hereafter, be referred to in this Section as “Table 1.”

Table 3.x.2-y - where ‘3’ indicates the LRA section number, ‘x’ indicates the subsection number from NUREG-1801, and ‘2’ indicates that this is the second table type in Section 3; and ‘y’ indicates the table number for a specific system. For example, for the Reactor Vessel, within Section 3.1 for the Reactor Pressure Vessel, this would be Table 3.1.2-1, and for the Reactor Vessel Internals, it would be Table 3.1.2-2. For the Combustible Gas Control System, within the ESF subsection, this table would be 3.2.2-1. For the next system within the ESF subsection, it would be Table 3.2.2-2. For ease of discussion, this Table will, hereafter, be referred to in this section as “Table 2.”

TABLE DESCRIPTION

NUREG-1801 contains the generic evaluation of existing plant programs. It documents the technical basis for determining where existing programs are adequate without modification, and where existing programs should be augmented for the extended period of operation. The evaluation results documented in NUREG-1801 indicate that many of the existing programs are adequate to manage the aging effects for particular structures or components, within the scope of LR, without change. NUREG-1801 also contains recommendations on specific areas for which existing programs should be augmented for LR. In order to take full advantage of NUREG-1801, a comparison between the CPNPP AMR results and the tables of NUREG-1801 has been performed. The results of that comparison are provided in the two tables.

Table 1

The purpose of Table 1 is to provide a summary comparison of how the facility aligns with the corresponding tables of NUREG-1800. The table is essentially the same as Tables 3.1-1 through 3.6-1 provided in NUREG-1800, except that the “ID” and “Type” columns have been replaced by an “Item Number” column, and the “Rev2 Item” and “Rev1 Item” columns have been replaced by a “Discussion” column.

The “Item Number” column provides the reviewer with a means to cross-reference from Table 2 to Table 1.

The “Discussion” column is used to provide clarifying or amplifying information. The following are examples of information that might be contained within this column:

- “Further Evaluation Recommended” information or reference to where that information is located.
- The name of a plant-specific AMP being used, if applicable.
- Exceptions to the NUREG-1800 assumptions, if applicable.
- A discussion of how the line is consistent with the corresponding line item in NUREG-1800, when additional plant-specific detail may provide clarity.
- A discussion of how the item is different than the corresponding line item in NUREG-1800 when it may appear to be consistent (e.g., when there is exception taken to an AMP that is listed in NUREG-1800), if applicable.

The format of Table 1 provides the reviewer with a means of aligning a specific Table 1 row with the corresponding NUREG-1800 Table row, thereby, allowing for the ease of checking consistency.

Table 2

Table 2 provides the detailed results of the AMRs for those components identified in Section 2 as being subject to AMR.

There will be a Table 2 for each of the systems within a Chapter 3 Section grouping. For example, for CPNPP, the ESF System Group contains tables specific to the CGCS, CSS, RHRS, and SIS.

Table 2 consists of the following nine columns:

- Component Type
- Intended Function
- Material
- Environment
- Aging Effect Requiring Management
- AMPs
- NUREG-1801 Item
- Table 1 Item
- Notes

Component Type – The first column identifies all of the component types from Section 2 of the LRA that are subject to AMR. They are listed in alphabetical order.

Intended Function – The second column contains the LR intended functions for the listed component types. Definitions of intended functions are contained in Table 2.1-1.

Material – The third column lists the particular materials of construction for the component type.

Environment – The fourth column lists the environments to which the component types are exposed. Service environments are indicated, and a list of these environments is provided in Tables 3.0-1, 3.0-2, and 3.0-3.

Aging Effect Requiring Management – As part of the AMR process, the aging effects that are required to be managed in order to maintain the intended function of the component type are identified for the material and environment combination. These aging effects requiring management are listed in the fifth column.

Aging Management Programs – The AMPs used to manage the aging effects requiring management are listed in the sixth column of Table 2. AMPs are described in Appendix B.

NUREG-1801 Item – Each combination of component type, material, environment, aging effect requiring management (AERM), and AMP that is listed in Table 2, is compared to NUREG-1801, with consideration given to the standard notes, to identify consistency. Consistency is documented by noting the appropriate NUREG-1801 item number in the seventh column of Table 2. If there is no corresponding item number in NUREG-1801, this field in column seven is left blank. Thus, a reviewer can readily identify the correlation between the plant-specific tables and the NUREG-1801 tables.

Table 1 Item – Each combination of component, material, environment, AERM, and AMP that has an identified NUREG- 1801 item number must also have a Table 3.x.1 line item reference number. The corresponding line item from Table 1 is listed in the eighth column of Table 2. If there is no corresponding item in NUREG-1801, this field in column eight is left blank. The Table 1 Item allows correlation of the information from the two tables.

Notes – The notes provided in each Table 2 describe how the information in the Table aligns with the information in NUREG-1801. Each Table 2 contains standard lettered notes and, if applicable, plant-specific numbered notes. The standard lettered notes (e.g., A, B, C) provide standard information regarding comparison of the CPNPP AMR results with the NUREG-1801 Aging Management Table line item identified in the seventh column. In addition to the standard lettered notes, numbered plant-specific notes provide additional clarifying information when appropriate.

TABLE USAGE

Table 1

The reviewer evaluates each row in Table 1 by moving from left to right across the table. Since the Component, Aging Effect, AMPs, and FE Recommended information is taken directly from NUREG-1800, no further analysis of those columns is required. The information intended to help the reviewer the most in this Table is contained within the Discussion column. Here the reviewer will be given plant-specific information necessary to determine, in summary, how the CPNPP evaluations and programs align with NUREG-1800. This may be in the form of descriptive information within the Discussion column, or the reviewer may be referred to other locations within the LRA for further information.

Table 2

Table 2 contains all of the AMR information for the plant, whether or not it aligns with NUREG-1801. For a given row within the table, the reviewer is able to see the intended function, material, environment, AERM and AMP combination for a particular component type within a system. In addition, if there is a correlation between the combination in Table 2 and a combination in NUREG-1801, this will be identified by a referenced item number in column seven, NUREG-1801 Item. The reviewer can refer to the item number in NUREG-1801, if desired, to verify the correlation. If the column is blank, no corresponding combination in NUREG-1801 was found. As the reviewer continues across the Table from left to right, within a given row, the next column is labeled Table 1 Item. If there is a reference number in this column, the reviewer is able to use that reference number to locate the corresponding row in Table 1 and see how the AMP for this particular combination aligns with NUREG-1801.

Table 2 provides the reviewer with a means to navigate from the components subject to AMR in Section 2 all the way through the evaluation of the programs that will be used to manage the effects of aging of those components. A listing of the acronyms used in this section is provided in Section 1.6.

Cumulative Fatigue Damage and TLAAs in Table 2

A fatigue analysis is considered to be a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3 when it is within the CLB and is based upon transient cycle assumptions associated with 40 years of plant operation. This includes explicit ASME Section III, Class 1 analyses for piping and components and implicit ASME Section III, Class 2 and 3 and ANSI B31.1 analyses for piping. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1).

Table 1 and Table 2 include an entry in the AMP column indicating "TLAA" for each line item that has a component for which a fatigue TLAA (explicit or implicit) has been identified. See Section 4.3 for details regarding the CPNPP fatigue design bases, fatigue TLAAs identified, and TLAA evaluations for the PEO.

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Air – dry	Compressed air of suitable quality and pressure for operation of instruments and controls, actuation of valves, dampers, and similar devices during various modes of plant operation. That is, air that has been treated to a) reduce its dew point well below the system operating temperature and b) control lubricant content, particulate matter, and other corrosive contaminants.	Air, dry
Air – indoor controlled	Ambient air in a humidity-controlled (i.e., air-conditioned) environment. Air that has been conditioned to reduce the humidity and dew point. Control room habitability encompasses all areas within the control room envelope (CRE) requiring occupancy during a hazardous chemical or radiological release or a smoke challenge.	Air – indoor controlled
Air – indoor uncontrolled	Ambient air for indoor locations that are sheltered/protected from weather (e.g., precipitation). Surfaces are normally dry, except in areas of leakage or water pooling, such as due to leakage or spills (not readily cleaned by housekeeping), which are considered the most susceptible locations for corrosion. Where indoor temperatures are ≥ 95°F, thermal aging of elastomers can occur. Where systems operate below the dew point, a “Condensation” environment is assigned.	Air – indoor uncontrolled; Air – indoor uncontrolled >35°C (>95°F) (Internal/External)
Air – outdoor	The outdoor environment consists of atmospheric air, ambient temperature and humidity, and exposure to weather, including precipitation and wind. Pooling of rainwater or perched water may occur in pits, vaults or tunnels or low points in the yard. The outdoor environment also potentially includes component contamination due to animal infestation including by-products or excrement containing uric acid, ammonia, phosphates, or other compounds.	Air – outdoor

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Air with borated water leakage	A subset of the Air-indoor uncontrolled and Air – outdoor environment that is used only for susceptible component materials located within buildings or areas that have systems containing borated water as they may be exposed to leakage and subsequent boric acid corrosion. Pertinent CPNPP buildings and locations include: • AB • FB • RCB • SGB (including the tunnel from RWST) Select yard locations (e.g., near the RWST)	Air with borated water leakage
Air with steam or water leakage	A subset of Air - indoor uncontrolled or Air – outdoor environments with steam or water leakage, such as onto or from system closure bolting, both below and above the dewpoint.	Air with steam or water leakage
Closed-cycle cooling water	Demineralized, treated water subject to closed-cycle cooling water chemistry control. Closed-cycle cooling water removes heat from various safety and non-safety related heat exchangers/coolers and is transferred in a closed loop to the other systems and then the UHS. Where the temperatures are > 140°F, the environment includes that indication for cracking in stainless steel.	Closed-cycle cooling water; Closed-cycle cooling water > 140°F
Concrete	Components in contact with concrete, that sit on or are embedded in foundations, floors, walls, etc. This does not include wall penetrations. Concrete is also a structural material that is subject to AMR. Embedded/reinforcing components are only susceptible to degradation if there has been groundwater or other water in-leakage; otherwise, the concrete forms a tight seal.	Concrete

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Condensation	Condensation on surfaces of systems at temperatures below the dew point. Moisture in the air is also considered to be condensation as it may promote degradation due to hygroscopic surface contaminants. Condensation can also form between thermal insulation and a component when air intrusion occurs through minor gaps in the insulation and the operating temperature of the component is below the dew point of the penetrating air. In addition, “waste gas” is typically held-up for a time, processed and released to the atmosphere. This waste gas may contain contaminants or moisture and so is included with “Condensation”.	Air, moist; Condensation
Diesel exhaust	Gases, fluids, particulates present in diesel engine exhaust.	Diesel exhaust
Fuel oil	Diesel oil, No. 2 oil, or other liquid hydrocarbons used to fuel diesel engines.	Fuel oil
Gas	Internal dry non-corrosive gas such as argon, halon, hydrogen, oxygen, and nitrogen. Argon, hydrogen, oxygen, and nitrogen gases are supplied to various plant system components on a continuous or intermittent basis. Halon is supplied to pertinent portions of the CPNPP fire suppression system. Refrigerant gas is provided for the safety chilled water and other pertinent systems.	Gas

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Lubricating oil	Lubricating oils are low to medium viscosity hydrocarbons used for bearing, gear, and engine lubrication. Hydraulic fluids are considered with lubricating oil. Lubricating oils can contain contaminants (water or particulates) but otherwise typically coat and protect surfaces. Lubricating oil that leaks from a component such as a RCP/motor is considered to contain potential contaminants such as water and dirt and is therefore, unique.	Lubricating oil
Raw water	Raw, untreated surface or groundwater; fresh, brackish, or saline water from an open, oxygen-rich source. This includes water in open-cycle cooling water systems and potable water for drinking or other personal use.	Raw water
Reactor coolant	Treated borated water in the RCS and connected systems at or near full operating temperature, including wet steam in the Pressurizer. Reactor coolant is >140°F and the temperature is not included in the environment. Also, temperatures are above >482°F and the temperature is not included in the environment.	Reactor coolant; Reactor coolant >250°C (>482°F); Reactor coolant >250°C (>482°F) and neutron flux;
Reactor coolant and neutron flux	The reactor core/vessel environment that will result in a neutron fluence exceeding 10^{17} n/cm^2 (E >1 MeV). For RVI components, high fluence (10^{21} n/cm^2 E > 0.1 MeV) is also a consideration of the environment.	Reactor coolant and neutron flux; Reactor coolant and high fluence (>1 x 10^{21} n/cm^2 E >0.1 MeV)
Soil	External environment for components at the air/soil interface, buried in the soil; or exposed to groundwater in the soil. Soil is a mixture of inorganic materials produced by the weathering of rock and clay minerals, and organic material produced by the decomposition of vegetation. Voids containing air and moisture occupy 30–60 percent of the soil volume. Properties of soil that can affect degradation include moisture content, pH, ion exchange capacity, density, and hydraulic conductivity.	Soil

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Steam	Steam, subject to a water chemistry program. In determining aging effects, steam is considered treated water. Steam is high temperature and defining the temperature is not necessary.	Steam; Reactor coolant and secondary feedwater/steam; Secondary feedwater/steam.
Treated borated water	Treated or demineralized borated water. Above the following thresholds, the temperature may be included with the environment: • >140°F – (SCC of stainless steel) • >270°F – (fatigue of stainless steel) • >482°F – (thermal embrittlement of CASS) • >500°F – (PWSCC of Alloy 600 nickel alloy)	Treated borated water; Treated borated water >60°C (>140°F); Treated borated water >250°C (>482°F); System temperature up to 340°C (644°F)
Treated water	Treated water is demineralized water and is the base water for all clean systems. Generally, contains minimal amounts of any additions and is generally characterized by high purity, low conductivity, and very low oxygen content. May, but need not be based on demineralized water, and contains corrosion inhibitors and also may contain biocides or other additives. This treated water will be comparatively higher in conductivity and oxygen content. Above the following thresholds, the temperature may be included with the environment: • >140°F – (SCC of stainless steel) • >220°F – (fatigue of carbon steel) • >482°F – (thermal embrittlement of CASS)	Treated water; Treated water >60°C (>140°F)

Table 3.0-1
Mechanical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Underground	Underground piping and tanks are below grade but are contained within a tunnel, pit, or vault such that they are in contact with air and are located where access for inspection is limited (e.g., special lifting equipment is required to gain access to the vault). When the underground environment is cited, the term includes exposure to air-outdoor, air-indoor uncontrolled, air, raw water, groundwater, or condensation. For CPNPP, the term underground may also be used to denote location below-grade or buried depending on the context of the statement (and should not be confused with the underground environment).	Underground
Waste water	Waters that are collected from equipment and floor drains. Waste waters may contain contaminants, including oil and boric acid, depending on location, as well as originally treated water that is not monitored by a chemistry program (Water may or may not be radioactive).	Waste water

Table 3.0-2
Structural Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Air – indoor uncontrolled	Ambient air for indoor locations that are sheltered/protected from weather (e.g., precipitation). Surfaces are normally dry, except in areas of leakage or water pooling, such as due to leakage or spills (not readily cleaned by housekeeping), which are considered the most susceptible locations for corrosion. Where indoor temperatures are ≥ 95°F, thermal aging of elastomers can occur. Where systems operate below the dew point, a "Condensation" environment is assigned.	Air – indoor uncontrolled; Air – indoor uncontrolled >35°C (>95°F) (Internal/External)
Air – outdoor	The outdoor environment consists of atmospheric air, ambient temperature and humidity, and exposure to weather, including precipitation and wind. Pooling of rainwater or perched water may occur in pits, vaults or tunnels or low points in the yard. The outdoor environment also potentially includes component contamination due to animal infestation including by-products or excrement containing uric acid, ammonia, phosphates, or other compounds.	Air – outdoor
Air with borated water leakage	A subset of the Air-indoor uncontrolled and Air – outdoor environment that is used only for susceptible component materials located within buildings or areas that have systems containing borated water as they may be exposed to leakage and subsequent boric acid corrosion. Pertinent CPNPP buildings and locations include: • AB • FB • RCB • SGB (including the tunnel from the RWST) Select yard locations (e.g., near the RWST)	Air with borated water leakage

Table 3.0-2
Structural Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Concrete	Components in contact with concrete, that sit on or are embedded in foundations, floors, walls, etc. This does not include wall penetrations. Concrete is also a structural material that is subject to AMR. Embedded/reinforcing components are only susceptible to degradation if there has been groundwater or other water in-leakage; otherwise, the concrete forms a tight seal.	Concrete
Groundwater/soil	Groundwater is subsurface water that can be detected in wells, tunnels, or drainage galleries, or that flows naturally to the earth's surface via seeps or springs. Groundwater is a part of the natural water cycle. Some part of the precipitation that lands on the ground surface infiltrates into the subsurface. The part that continues downward through the soil until it reaches rock material that is saturated is groundwater recharge. Water in the saturated groundwater system moves slowly and may eventually discharge into streams, and lakes. The ground above the water table may be wet to a certain degree, but it does not stay saturated. The dirt and rock in this unsaturated zone contain air and some water. At CPNPP, groundwater is not expected to reach higher than EL. 775-ft. Aggressive contaminants for underground concrete are those which have a pH <5.5 and/or chlorides >500 ppm and/or sulfides >1500 ppm. CPNPP groundwater is non-aggressive, as discussed further in item 4 of Section 3.5.2.2.2.1.	Groundwater/soil
Soil	External environment for components at the air/soil interface, buried in the soil; or exposed to groundwater in the soil. Soil is a mixture of inorganic materials produced by the weathering of rock and clay minerals, and organic material produced by the decomposition of vegetation. Voids containing air and moisture occupy 30–60 percent of the soil volume. Properties of soil that can affect degradation include moisture content, pH, ion exchange capacity, density, and hydraulic conductivity.	Soil

Table 3.0-2
Structural Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Treated borated water	Treated or demineralized borated water. Above the following thresholds, the temperature may be included with the environment: • >140°F – (SCC of stainless steel) • >270°F – (fatigue of stainless steel) • >482°F – (thermal embrittlement of CASS) • >500°F – (PWSCC of Alloy 600 nickel alloy)	Treated borated water; Treated borated water >60°C (>140°F); Treated borated water >250°C (>482°F); System temperature up to 340°C (644°F)
Water - flowing	Water that is refreshed; thus, it has a greater impact on leaching and can include rainwater, raw water, groundwater, or water flowing under a foundation.	Water-flowing
Water - standing	Water that is stagnant and unrefreshed, thus possibly resulting in increased ionic strength up to saturation.	Water-standing

Table 3.0-3
Electrical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Adverse localized environment caused by heat, radiation, or moisture Adverse localized environment caused by significant moisture	An adverse localized environment (ALE) is an environment limited to the immediate vicinity of a component that is hostile to the component material, thereby leading to potential aging effects. As used in GALL, the conductor insulation used for electrical cables in instrumentation circuits can be subjected to an ALE. As represented by a specific GALL AMR Item, an ALE can be due to either of the following: (1) exposure to significant moisture or (2) heat, radiation, or moisture.	Adverse localized environment caused by heat, radiation, or moisture
Air – indoor controlled	This environment is one to which the specified internal or external surface of the component or structure is exposed; a humidity-controlled (i.e., air conditioned) environment. For electrical purposes, control must be sufficient to eliminate the cited aging effects of contamination and oxidation without affecting the resistance.	Air – indoor controlled
Air – indoor uncontrolled	Uncontrolled indoor air is associated with systems with temperatures higher than the dew point (i.e., condensation can occur, but only rarely; equipment surfaces are normally dry).	Air – indoor uncontrolled
Air – outdoor	The outdoor environment consists of atmospheric air, ambient temperature and humidity, and exposure to weather, including precipitation and wind. Pooling of rainwater or perched water may occur in pits, vaults or tunnels or low points in the yard. The outdoor environment also potentially includes component contamination due to animal infestation including by-products or excrement containing uric acid, ammonia, phosphates, or other compounds.	Air – outdoor
Air with borated water leakage	Air and untreated borated water leakage on indoor or outdoor systems with temperatures either above or below the dew point. The water from leakage is considered to be untreated, due to the potential for water contamination at the surface.	Air with borated water leakage

Table 3.0-3
Electrical Service Environments

Environment	Description	Corresponding NUREG-1801 Environments
Soil	Soil is a mixture of inorganic materials produced by the weathering of rock and clay minerals, and organic material produced by the decomposition of vegetation. Voids containing air and moisture occupy 30 to 60 percent of the soil volume. Properties of soil that can affect degradation kinetics include moisture content, pH, ion exchange capacity, density, and hydraulic conductivity. External environments included in the soil category consist of components at the air/soil interface, buried in the soil, or exposed to ground water in the soil.	Soil

3.1. AGING MANAGEMENT OF REACTOR VESSEL, INTERNALS, AND REACTOR COOLANT SYSTEM

3.1.1. Introduction

This section provides the results of the AMR for those components identified in Section 2.3.1, "Reactor Vessel, Internals, and Reactor Coolant System, as being subject to AMR". The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Reactor Vessel (2.3.1.1)
- Reactor Vessel Internals (2.3.1.2)
- Reactor Coolant System and Attached Piping (2.3.1.3)
- Steam Generators (2.3.1.4)

3.1.2. Results

The following tables summarize the results of the AMR for the Reactor Vessel, Internals, and Reactor Coolant System.

Table 3.1.2-1: Reactor Vessel - Summary of Aging Management Evaluation

Table 3.1.2-2: Reactor Vessel Internals - Summary of Aging Management Evaluation

Table 3.1.2-3: Reactor Coolant System and Attached Piping - Summary of Aging Management Evaluation

Table 3.1.2-4: Steam Generators - Summary of Aging Management Evaluation

3.1.2.1. Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.1.2.1.1. Reactor Pressure Vessel

Materials

The materials of construction for the RPV components are:

- Carbon steel
- Carbon steel with stainless steel cladding
- Nickel alloy
- Stainless steel

Environments

The RPV components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage

- Reactor coolant
- Reactor coolant with neutron flux

Aging Effects Requiring Management

The following aging effects associated with the RPV require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Reduction in fracture toughness

Aging Management Programs

The following AMPs manage the aging effects for the RPV components:

- ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1)
- Boric Acid Corrosion (B.2.3.4)
- Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5)
- Flux Thimble Tube Inspection (B.2.3.23)
- Reactor Head Closure Stud Bolting (B.2.3.3)
- Reactor Vessel Surveillance (B.2.3.18)
- TLAA (Sections 4.3 and 4.4)
- Water Chemistry (B.2.3.2)

3.1.2.1.2. Reactor Vessel Internals

Materials

The materials of construction for the RVI components are:

- CASS
- Nickel alloy
- Stainless steel

Environment

The RVI components are exposed to:

- Reactor coolant and neutron flux

Aging Effects Requiring Management

The following aging effects associated with the RVI require management:

- Change in dimension
- Cracking

- Cumulative fatigue damage
- Loss of fracture toughness
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the RVI components:

- ASME Section XI, Inservice Inspection, Subsections IWB, IWC and IWD (B.2.3.1)
- PWR Vessel Internals (B.2.3.7)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.1.2.1.3. Reactor Coolant System and Attached Piping

Materials

The materials of construction for the RCS and attached piping are:

- Carbon steel
- Carbon steel with stainless steel cladding
- CASS
- Copper alloy
- Elastomer
- Nickel alloy
- Stainless steel (including CASS, centrifugal)

Environments

The RCS and attached piping are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Gas
- Lubricating oil
- Reactor coolant (including steam)
- Treated borated water
- Treated borated water > 140°F
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the RCS and attached piping require management:

- Cracking
- Cumulative fatigue damage

- Hardening and loss of strength
- Loss of material
- Loss of preload
- Reduction in fracture toughness

Aging Management Programs

The following AMPs manage the aging effects for the RCS and attached piping:

- ASME Section XI Inservice Inspection, Subsection IWB, IWC, and IWD (B.2.3.1)
- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- One-Time Inspection of ASME Code Class 1 Small-Bore Piping (B.2.3.21)
- Thermal Aging Embrittlement of CASS (B.2.3.6)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.1.2.1.4. Steam Generators

Materials

The materials of construction for the SG subcomponents are:

- Carbon steel
- Carbon steel with nickel alloy cladding
- Carbon steel with stainless steel cladding
- Nickel alloy
- Stainless steel

Environments

The SG subcomponents are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Reactor coolant
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the SG subcomponents require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the SG subcomponents:

- ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1)
- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- Steam Generators (B.2.3.10)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.1.2.2. AMR Results for Which Further Evaluation is Recommended by the GALL Report

The AMR summaries for the CPNPP Reactor Vessel, Internals, and Reactor Coolant System provide the basis for Section 3.1.2.2. NUREG-1801 provides the basis for identifying those programs that warrant FE by the reviewer in the LRA. For the Reactor Vessel, Internals, and Reactor Coolant System, those programs are addressed in the following subsections.

Note - *Italicized* text is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-04, LR-ISG-2011-05, LR-ISG-2016-01, and SLR-ISG-2021-01-PWRVI.

3.1.2.2.1. Cumulative Fatigue Damage

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

Where identified as an AERM, in Table 3.1-1, the analysis of fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are evaluated in accordance with 10 CFR 54.21(c). Evaluation of this TLAA is addressed in Section 4.3.

3.1.2.2.2. Loss of Material due to General, Pitting, and Crevice Corrosion

1. *Loss of material due to general, pitting, and crevice corrosion could occur in the steel PWR steam generator upper and lower shell and transition cone exposed to secondary feedwater and steam. The existing program relies on control of water chemistry to mitigate corrosion and Inservice Inspection (ISI) to detect loss of material. The extent and schedule of the existing steam generator inspections are designed to ensure that flaws cannot attain a depth sufficient to threaten the integrity of the welds. However, according to NRC Information Notice (IN) 90-04, the program may not be sufficient to detect pitting and crevice corrosion, if general and pitting corrosion of the shell is known to exist. The GALL Report recommends augmented inspection to manage this aging effect. Furthermore, the GALL Report clarifies that this issue is limited to Westinghouse Model 44 and 51 Steam Generators, where a high-stress region exists at the shell to transition cone weld. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Loss of material due to general, pitting, and crevice corrosion could occur in the steel PWR SG upper and lower shell and transition cone exposed to secondary feedwater and steam, but do not require augmented inspection. The CPNPP Unit 1 SGs are Westinghouse Model Delta 76 and the Unit 2 SGs are Westinghouse Model D-5. Augmented inspections recommended for Westinghouse Model 44 and 51 SGs are not required for the CPNPP Delta 76 and D-5 SGs as discussed in item 3.1-1, 012.

2. *Loss of material due to general, pitting, and crevice corrosion could occur in the steel PWR steam generator shell assembly exposed to secondary feedwater and steam. The existing program relies on control of secondary water chemistry to mitigate corrosion. However, some applicants have replaced only the bottom part of their recirculating steam generators, generating a cut in the middle of the transition cone, and, consequently, a new transition cone closure weld. The GALL Report recommends volumetric examinations performed in accordance with the requirements of ASME Code Section XI for upper shell-to and lower shell-to transition cones with gross structural discontinuities for managing loss of material due to general, pitting, and crevice corrosion in the welds for Westinghouse Model 44 and 51 Steam Generators, where a high-stress region exists at the shell to transition cone weld.*

   The new continuous circumferential weld, resulting from cutting the transition cone as discussed above, is a different situation from the SG transition cone welds containing geometric discontinuities. Control of water chemistry does not preclude loss of material due to pitting and crevice corrosion at locations of stagnant flow conditions. The new transition area weld is a field-weld as opposed to having been made in a *controlled manufacturing facility, and the surface conditions of the transition weld may result in flow conditions more conducive to initiation of general, pitting, and crevice corrosion than those of the upper and lower transition cone welds. Crediting of the ISI program for the new SG transition cone weld may not be an effective basis for managing loss of material in this weld, as the ISI criteria would only perform a VT-2 visual leakage examination of the weld as part of the system leakage test performed pursuant to ASME Section XI requirements. In addition, ASME Section XI does not require licensees to remove insulation when performing visual examination on non-borated treated water systems. Therefore, the effectiveness of the chemistry control program should be verified to ensure that loss of material due to general, pitting and crevice corrosion is not occurring.*

For the new continuous circumferential weld, the GALL Report recommends further evaluation to verify the effectiveness of the chemistry control program. A one-time inspection at susceptible locations is an acceptable method to determine whether an aging effect is not occurring or an aging effect is progressing very slowly, such that the component's intended function will be maintained during the period of extended operation. Furthermore, the GALL Report clarifies that this issue is limited to replacement recirculating steam generators with a new transition cone closure weld.

The Unit 1 model Delta 76 replacement SGs were complete replacements and therefore the Unit 1 SGs do not have a circumferential field weld. The Unit 2 SGs are original to the plant and therefore also do not have a circumferential field weld. Note that the inspections of the original SG transition cone welds on both units will continue to be performed consistent with the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP, as discussed in item 3.1-1, 012.

3.1.2.2.3. <u>Loss of Fracture Toughness due to Neutron Irradiation Embrittlement</u>

1. *Neutron irradiation embrittlement is a TLAA to be evaluated for the period of extended operation for all ferritic materials that have a neutron fluence greater than 10^{17} n/cm^2 (E >1 MeV) at the end of the license renewal term. Certain aspects of neutron irradiation embrittlement are TLAAs as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c)(1). This TLAA is addressed separately in Section 4.2, "Reactor Vessel Neutron Embrittlement Analysis," of this SRP-LR.*

As discussed in item 3.1-1, 013, loss of fracture toughness due to neutron irradiation embrittlement is an aging effect and mechanism evaluated for the reactor vessel beltline and extended beltline by a TLAA. The TLAA evaluation of neutron irradiation embrittlement is discussed in Section 4.2, "Reactor Vessel Neutron Embrittlement."

2. *Loss of fracture toughness due to neutron irradiation embrittlement could occur in BWR and PWR reactor vessel beltline shell, nozzle, and welds*

exposed to reactor coolant and neutron flux. A reactor vessel materials surveillance program monitors neutron irradiation embrittlement of the reactor vessel. The reactor vessel surveillance program is plant-specific, depending on matters such as the composition of limiting materials, availability of surveillance capsules, and projected fluence levels. In accordance with NUREG-1800, Rev. 2 3.1-4 December 2010 10 CFR Part 50, Appendix H, an applicant is required to submit its proposed withdrawal schedule for approval prior to implementation. Untested capsules placed in storage must be maintained for future insertion. Thus, further staff evaluation is required for license renewal. Specific recommendations for an acceptable AMP are provided in Chapter XI, Section M31 of the GALL Report.

As discussed in item 3.1-1, 014, loss of fracture toughness due to neutron irradiation embrittlement could occur in the reactor vessel shells, nozzles, and welds. The neutron fluence TLAA is discussed in Section 4.2.1, "Neutron Analysis". The fluence is a time-limited input to the Reactor Vessel Embrittlement TLAA beltline and extended beltline (e.g., nozzle) materials as discussed in Sections 4.2.2 through 4.2.5. The Reactor Vessel Material Surveillance AMP, which includes an exception to NUREG-1801 Section XI.M31, manages reduction in fracture toughness due to neutron embrittlement of reactor vessel beltline and extended beltline (e.g., nozzle) materials. This program, which uses CPNPP surveillance capsule data, monitors changes in the fracture toughness properties of ferritic materials in the RPV beltline and extended beltline region.

3. *Ductility – Reduction in Fracture Toughness is a plant-specific TLAA for Babcock and Wilcox (B&W) reactor internals to be evaluated for the period of extended operation in accordance with the staff's safety evaluation concerning "Demonstration of the Management of Aging Effects for the Reactor Vessel Internals," Babcock and Wilcox Owners Group report number BAW-2248, which is included in BAW-2248A, March 2000. Plant-specific TLAAs are addressed in Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-LR.*

Not applicable, as discussed in item 3.1-1, 015. This FE item is only applicable to Babcock & Wilcox reactor internals.

3.1.2.2.4. <u>Cracking due to Stress Corrosion Cracking and Intergranular Stress Corrosion Cracking</u>

1. *Cracking due to stress corrosion cracking (SCC) and intergranular stress corrosion cracking (IGSCC) could occur in the stainless steel and nickel alloy BWR top head enclosure vessel flange leak detection lines. The GALL Report recommends that a plant-specific AMP be evaluated because existing programs may not be capable of mitigating or detecting cracking due to SCC and IGSCC. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Not applicable. This FE item is applicable to BWRs only, as listed in item 3.1-1, 016.

2. Cracking due to SCC and IGSCC could occur in stainless steel BWR isolation *condenser components exposed to reactor coolant. The existing program relies on control of reactor water chemistry to mitigate SCC and on ASME Section XI IS I to detect cracking. However, the existing program should be augmented to detect cracking due to SCC and IGSCC. The GALL Report recommends an augmented program to include temperature and radioactivity monitoring of the shell-side water and eddy current testing of tubes to ensure that the component's intended function will be maintained during the period of extended operation. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Not applicable. This FE item is applicable to BWRs only, as listed in item 3.1-1, 017.

3.1.2.2.5. Crack Growth due to Cyclic Loading

Crack growth due to cyclic loading could occur in reactor vessel shell forgings clad with stainless steel using a high-heat-input welding process. Growth of intergranular separations (underclad cracks) in the heat-affected zone under austenitic stainless steel cladding is a TLAA to be evaluated for the period of extended operation for all the SA-508-Cl-2 forgings where the cladding was deposited with a high heat input welding process.

All applicable SA-508-Cl-2 forgings at CPNPP Units 1 and 2 are not affected by underclad cracking due to the control of the cladding welding process in accordance with RG 1.43. These applicable components include the Unit 1 reactor vessel flange, Unit 1 primary inlet and outlet nozzles, Unit 2 closure head flange, Unit 2 reactor vessel flange, and Unit 2 primary inlet and outlet nozzles. Welding specifications pertaining to these applicable components were reviewed and determined to meet the intent of RG 1.43, regarding the use of low heat input welding techniques. As a result, the underclad cracking TLAA is not applicable to CPNPP Units 1 and 2 for LR, as discussed in item 3.1-1, 018 and noted in Table 4.1-1.

3.1.2.2.6. Cracking due to Stress Corrosion Cracking

1. *Cracking due to SCC could occur in the PWR stainless steel reactor vessel flange leak detection lines and bottom-mounted instrument guide tubes exposed to reactor coolant. The GALL Report recommends further evaluation to ensure that these aging effects are adequately managed. The GALL Report recommends that a plant-specific AMP be evaluated to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

As discussed in item 3.1-1, 019, the effects of cracking due to SCC in the stainless steel BMI guide tubes (external to the RV bottom head to the seal table) and reactor vessel flange leak detection components will be managed using the Water Chemistry (B.2.3.2) AMP and the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP. The Water Chemistry (B.2.3.2)

AMP will minimize the contaminants in the reactor coolant which promote SCC. VT-2 inspections are performed as a part of the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP and will identify degradation of the stainless steel BMI guide tubes and reactor vessel flange leak detection components. A plant-specific program is not required.

2. *Cracking due to SCC could occur in Class 1 PWR cast austenitic stainless steel (CASS) reactor coolant system piping, piping components, and piping elements exposed to reactor coolant. The existing program relies on control of water chemistry to mitigate SCC; however, SCC could occur for CASS components that do not meet the NUREG-0313 guidelines with regard to ferrite and carbon content. The GALL Report recommends further evaluation of a plant-specific program for these components to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

As discussed in item 3.1-1, 020, cracking due to SCC could occur in CASS components that do not meet the NUREG-0313 guidelines regarding ferrite and carbon content. However, review of NUREG-0313 describes industry experience where SCC of CASS components occurred in BWRs primarily due to susceptible CASS components being exposed to BWR water chemistry with high levels of oxygen and other contaminants. NUREG-0313 does not identify SCC of CASS components as being problematic in PWRs like CPNPP. This can be attributed to the very tight controls of PWR water chemistry for dissolved oxygen and other aggressive contaminants. Therefore, the Water Chemistry (B.2.3.2) AMP will manage the aging effect of cracking due to SCC in Class 1 RCS CASS piping and piping components. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking due to SCC in Class 1 RCS CASS piping and piping components. The CPNPP disposition for Section 3.1.2.2.6, Item 2 is consistent with the disposition accepted for the Turkey Point Units 3 and 4 SLRA (Reference ML19191A057).

3.1.2.2.7. Cracking due to Cyclic Loading

Cracking due to cyclic loading could occur in steel and stainless steel BWR isolation condenser components exposed to reactor coolant. The existing program relies on ASME Section XI ISI. However, the existing program should be augmented to detect cracking due to cyclic loading. The GALL Report recommends an augmented program to include temperature and radioactivity monitoring of the shell-side water and eddy current testing of tubes to ensure that the component's intended function will be maintained during the period of extended operation. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Not applicable. This FE item is applicable to BWRs only, as listed in item 3.1-1, 021.

3.1.2.2.8. Loss of Material due to Erosion

Loss of material due to erosion could occur in steel steam generator feedwater impingement plates and supports exposed to secondary feedwater. The GALL Report recommends further evaluation of a plant-specific AMP to ensure that this aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

As discussed in item 3.1-1, 022, SG feedwater impingement plates and supports are not part of the Unit 1 SGs (model Delta 76) used at CPNPP. The Unit 2 SGs (model D-5) have stainless steel feedwater impingement plates and supports. Therefore, this item is not applicable at CPNPP, and a plant-specific program is not required.

3.1.2.2.9. Aging Management of Pressurized Water Reactor Vessel Internals (Applicable to Subsequent License Renewal Periods only)

Electric Power Research Institute (EPRI) Topical Report (TR)-1022863, "Materials Reliability Program: Pressurized Water Reactor Internals Inspection and Evaluation Guidelines (MRP-227-A)" (Agencywide Documents Access and Management System (ADAMS) Accession Nos. ML12017A191 through ML12017A197 and ML12017A199), provided the industry's initial set of aging management inspection and evaluation (I&E) recommendations for the reactor vessel internal (RVI) components that are included in the design of a PWR facility. Since the issuance of MRP-227-A on January 9, 2012, EPRI updated its I&E guidelines for the PWR RVI components in Topical Report No. 3002017168, "Materials Reliability Program: Pressurized Water Reactor Internals Inspection and Evaluation Guidelines (MRP-227, Revision 1-A)" (ADAMS Accession No. ML20175A112). MRP-227, Revision 1-A, incorporated the industry's bases for resolving operating experience and industry lessons learned resulting from component-specific inspections performed since the issuance of MRP-227-A in January 2012. The staff found the guidelines in MRP-227, Revision 1-A, acceptable, as documented in a staff-issued safety evaluation dated April 25, 2019 (ADAMS Accession No. ML19081A001) and approved the topical report for use as documented in the staff's letters to the EPRI Materials Reliability Program (MRP) dated February 19, 2020 and July 7, 2020 (ADAMS Accession Nos. ML20006D152 and ML20175A149).

In MRP-227, Revision 1-A, the EPRI MRP identified that the following aging mechanisms may be applicable to the design of the RVI components in these types of facilities: (a) stress corrosion cracking (SCC), (b) irradiation-assisted stress corrosion cracking (IASCC), (c) fatigue, (d) wear, (e) neutron irradiation embrittlement, (f) thermal aging embrittlement, (g) void swelling and irradiation growth or component distortion, and (h) thermal or irradiation-enhanced stress relaxation or irradiation enhanced creep.

The EPRI MRP's functionality analysis and failure modes, effects, and criticality analysis bases for grouping Westinghouse-designed, B&W-designed and Combustion Engineering (CE)-designed RVI components *into the applicable inspection categories (as evaluated in MRP-227, Revision 1-A) were based on an assessment of aging effects and relevant time-dependent aging parameters through a cumulative 60-year licensing period (i.e., 40 years for the initial operating license period plus an additional 20 years during the initial period of extended operation). The EPRI MRP's assessment in MRP-227, Revision 1-A, did not evaluate whether operation of Westinghouse-designed, B&W-designed and CE-designed reactors during an SLR operating period (60 to 80 years) would have any impact on the existing susceptibility rankings and inspection categorizations for the RVI components in these designs, as defined in MRP-227, Revision 1-A or the applicable MRP background documents (e.g., MRP-191, Revision 1, for Westinghouse-designed or CE-designed RVI components or MRP-189, Revision 2, for B&W-designed components).*

As described in GALL-SLR Report AMP XI.M16A, the applicant may use the MRP-227, Revision 1-A based AMP as an initial reference basis for developing and defining the AMP that will be applied to the RVI components for the subsequent period of extended operation. However, to use this alternative basis, GALL-SLR Report AMP XI.M16A recommends that the MRP-227, Revision 1-A based AMP be enhanced to include a gap analysis of the components that are within the scope of the AMP. The gap analysis is a basis for identifying and justifying changes to the MRP-227, Revision 1-A based program that are necessary to provide reasonable assurance that the effects of age-related degradation will be managed during the subsequent period of extended operation. The criteria for the gap analysis are described in GALL-SLR Report AMP XI.M16A. If a gap analysis is needed to establish the appropriate aging management criteria for the RVI components, the applicant has the option of including the gap analysis in the SLRA or making the gap analysis and any supporting gap analysis documents available in the in-office audit portal for the SLRA review.

Subsequent license renewal (SLR) applicants for units of a PWR design will no longer need to include separate SLRA Appendix C section responses in resolution of the A/LAIs previously issued on MRP-227-A because the A/LAIs were resolved and closed by the staff in the April 25, 2019, safety evaluation for MRP-227, Revision 1-A. The sole A/LAI issued by the staff in the safety evaluation dated April 25, 2019, relates to an applicant's methods and timing of inspections that will be applied to the baffle-to-former bolts or core shroud bolts in the plant design. Since an applicant's resolution of this A/LAI can be appropriately addressed in the "Operating Experience" program element discussion for the AMP and in the applicant's basis document for the AMP, a separate SLRA Appendix C response for the A/LAI is unnecessary.

Alternatively, the PWR SLRA may define a plant-specific AMP for the RVI components to demonstrate that the RVI components will be managed in accordance with the requirements of 10 CFR 54.21(a)(3) during the proposed subsequent period of extended operation. Components to be inspected, parameters monitored, monitoring methods, inspection sample size, frequencies, expansion criteria, and acceptance criteria are justified in the SLRA. If the AMP is a plant-specific program, the NRC staff will assess the adequacy of the plant-specific AMP against the criteria for the 10 AMP *program elements that are defined in Section A.1.2.3 of SRP-SLR Appendix A.1.*

LR-ISG-2011-04 removed FEs 3.1.2.2.9, 3.1.2.2.10, 3.1.2.2.12, 3.1.2.2.13 and 3.1.2.2.14 from NUREG-1800 Revision 2. LR-ISG-2021-01-PWRVI indicates that it supersedes previous guidance in their entirety and that the FE for 3.1.2.2.9 is applicable to SLR Periods Only. However, the MRP-227, Revision 1-A, identified aging mechanisms potentially applicable to the design of the RVI components are applicable to the CPNPP RVI. Furthermore, the RVI aging mechanisms formerly addressed by FE in NUREG-1800 Revision 2 sections 3.1.2.2.9, 3.1.2.2.10, 3.1.2.2.13, and 3.1.2.2.14 are now encompassed by the current 3.1.2.2.9. In addition, the susceptibility rankings and inspection categorizations from RVI components in MRP-227, Revision 1-A for 60 years of operation are applicable to CPNPP LR. As such, a plant-specific AMP (or failure modes and effects criticality analysis) is not necessary.

As discussed in items 3.1-1, 053a, 053b, and 053c, consistent with the guidance of SLR-ISG-2021-01-PWRVI, cracking (SCC/IASCC) will be managed by the PWR Vessel Internals (B.2.3.7) AMP and Water Chemistry (B.2.3.2) AMP for RVI components other than those in the 'no additional measures' MRP-227, Rev. 1-A categorization. Similarly, as discussed in items 3.1-1, 059a, 059b, 059c, and 119, change in dimension, loss of fracture toughness, loss of material and loss of preload of pertinent RVI components will be managed by the PWR Vessel Internals (B.2.3.7) AMP.

Both the flux thimble tubes and CRGT support (split) pins internal to the reactor vessel are categorized as 'no additional measures' components and will be managed by the PWR Vessel Internals (B.2.3.7) AMP, as discussed in item 3.1-1, 055c. The flux thimble tubes also receive an augmented inspection through the ASME Section XI, Subsections IWB, IWC, and IWD AMP.

3.1.2.2.10. Removed as a Result of LR-ISG-2011-04

See further evaluation 3.1.2.2.9 above.

3.1.2.2.11. Cracking due to Primary Water Stress Corrosion Cracking (per LR-ISG-2016-01)

1. *Foreign operating experience in steam generators with a design similar to that of Westinghouse steam generators (particularly Model 51) has identified cracks due to primary water stress corrosion cracking (PWSCC) in steam generator (SG) divider plate assemblies fabricated of Alloy 600 and/or the associated Alloy 600 weld materials, even with proper primary water chemistry. Cracks have been detected in the stub runner with depths typically about 0.08 inches (EPRI 3002002850).*

   All but one of these instances of cracking have been detected in divider plate assemblies that are approximately 1.3 inches in thickness. For the cracks in the 1.3-inch thick divider plate assemblies, the cracks tend to be parallel to the divider-plate-to-stub-runner weld (i.e., run horizontally in parallel to the lower surface of the tubesheet). For the one instance of cracking in a divider *plate assembly with a thickness greater than 1.3 inches, the cracking occurred in a divider plate assembly with a thickness of approximately 2.4 inches near manufacturing marks on the upper end of the stub runner used for locating tubesheet holes. These flaws were estimated to be approximately 0.08-inch deep.*

Although these instances indicate that the water chemistry program may not be sufficient to manage cracking due to PWSCC in SG divider plate assemblies, analyses by the industry indicate that PWSCC in the divider plate assembly does not pose a structural integrity concern for other steam generator components (e.g., tubesheet and tube-to-tubesheet welds) and does not adversely affect other safety analyses (e.g., analyses supporting tube plugging and repairs, tube repair criteria, and design basis accidents). In addition, the industry analyses indicate that flaws in the divider plate assembly will not adversely affect the heat transfer function (as a result of bypass flow) during normal forced flow operation, during natural circulation conditions (assessed in the analyses of various design basis accidents), or in the event of a loss-of-coolant accident (LOCA).

Furthermore, additional industry analyses indicate that PWSCC in the divider plate assembly is unlikely to adversely impact adjacent items, such as the tubesheet cladding, tube-to-tubesheet welds, and channel head. Therefore,

- *For units with divider plate assemblies fabricated of Alloy 690 and Alloy 690 type weld materials, a plant-specific aging management program (AMP) is not necessary.*

- *For units with divider plate assemblies fabricated of Alloy 600 or Alloy 600 type weld materials, if the analyses performed by the industry (EPRI 3002002850) are applicable and bounding for the unit, a plant-specific AMP is not necessary.*

- *For units with divider plate assemblies fabricated of Alloy 600 or Alloy 600 type weld materials, if the industry analyses (EPRI 3002002850) are not bounding for the applicant's unit, a plant-specific AMP is necessary or a rationale is necessary for why such a program is not needed. A plant-specific AMP (one beyond the primary water chemistry and the steam generator programs) may include a one-time inspection that is capable of detecting cracking to verify the effectiveness of the water chemistry and steam generator programs and the absence of PWSCC in the divider plate assemblies.*

The existing programs rely on control of reactor water chemistry to mitigate cracking due to PWSCC and general visual inspections of the channel head interior surfaces (included as part of the steam generator program). The GALL Report recommends further evaluation for a plant-specific AMP to confirm the effectiveness of the primary water chemistry and steam generator programs as described in this section. Acceptance criteria for a plant-specific AMP are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR). In place of a plant-specific AMP, the applicant may provide a rationale to justify why a plant-specific AMP is not necessary.

CPNPP Unit 1 Model Delta 76 SGs have an Alloy 690 divider plate assembly and a plant-specific AMP is not necessary. CPNPP Unit 2 Model D-5 SGs have an Alloy 600 divider plate assembly. The industry analysis (EPRI TR-3002002850) has been determined to be applicable and bounding for CPNPP Unit 2.

Because the analysis is applicable and bounding for CPNPP Unit 2, the Water Chemistry (B.2.3.2) AMP and Steam Generators (B.2.3.10) AMP will manage PWSCC in the divider plate through the PEO. Therefore, as discussed in item 3.1-1, 025, a plant-specific AMP is not necessary to verify the effectiveness of the Water Chemistry (B.2.3.2) AMP and Steam Generators (B.2.3.10) AMP.

2. *Cracking due to PWSCC could occur in steam generator nickel alloy tube-to-tubesheet welds exposed to reactor coolant. The acceptance criteria for this review are:*

    - *For units with Alloy 600 steam generator tubes that have not been thermally treated and for which an alternate repair criteria such as C*, F*, W*, or H* has been permanently approved for both the hot-and cold-leg side of the steam generator, the weld is no longer part of the reactor coolant pressure boundary and a plant-specific AMP is not necessary;*

    - *For units with Alloy 600 steam generator tubes that have not been thermally treated, if there is no permanently approved alternate repair criteria such as C*, F*, W*, or H* or permanent approval applies to only either the hot-or cold-leg side of the steam generator, a plant-specific AMP is necessary;*

    - *For units with thermally treated Alloy 690 steam generator tubes and with tubesheet cladding using Alloy 690 type material, a plant-specific AMP is not necessary;*

    - *For units with thermally treated Alloy 690 steam generator tubes and with tubesheet cladding using Alloy 600 type material, a plant-specific AMP is necessary unless the applicant confirms that the industry's analyses for tube-to-tubesheet weld cracking (e.g., chromium content for the tube-to-tubesheet welds is approximately 22 percent and the tubesheet primary face is in compression as discussed in EPRI 3002002850) are applicable and bounding for the unit, and the applicant will perform general visual inspections of the tubesheet region looking for evidence of cracking (e.g., rust stains on the tubesheet cladding) as part of the steam generator program. In lieu of a plant-specific AMP, the applicant may provide a rationale for why a plant-specific AMP is not necessary.*

    - *The existing programs rely on control of reactor water chemistry to mitigate cracking due to PWSCC and visual inspections of the steam generator head interior surfaces. Along with the primary water chemistry and steam generator programs, the GALL Report recommends further evaluation of a plant-specific AMP to confirm the effectiveness of the primary water chemistry and steam generator* *programs in certain circumstances. A plant-specific AMP may include a one-time inspection that is capable of detecting cracking to confirm the absence of PWSCC in the tube-to-tubesheet welds. Acceptance criteria for a plant-specific AMP are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR). In place of a plant-specific AMP, the applicant may provide a rationale to justify why a plant-specific AMP is not necessary.*

CPNPP Unit 1 Model Delta 76 SGs have an Alloy 690 divider plate assembly with Alloy 690 tubes and tube-to-tubesheet welds. CPNPP Unit 2 Model D-5 SGs have an Alloy 600 divider plate assembly with thermally treated Alloy 600 (A600TT) tubes.

The current examination criteria for Unit 2 comes from Westinghouse guidance for model D-5 SGs, issued in WCAP-17072-NP (Reference 1.7.39). This criteria was approved as a temporary alternate repair criteria (ARC) by the NRC on October 9, 2009 as Amendment 149 (Reference ML092740076) to the technical specification/operating license and approved as a permanent ARC in Amendment 158 (Reference ML12263A036) on October 18, 2012. The technical evaluation for this H* ARC also concludes that the tube-to-tubesheet weld for the Unit 2 SGs is not required to maintain the RCPB, which is an exception to the guidance in NUREG-1801, as the initial hydraulic expansion of the tubes against the tubesheet during construction creates an interference fit between the two components, producing a residual contact pressure which acts normally to the outer surface of the tubes and the inner surface of the tubesheet bore holes. Additional contact pressure between the tubes and tubesheet is further induced by operational conditions (Reference ML12263A036, Section 4.2).

The effectiveness of the Water Chemistry (B.2.3.2) AMP to manage PWSCC in the Unit 1 SG tube-to-tubesheet welds is verified by the Steam Generators (B.2.3.10) AMP. The Unit 2 SG does not require aging management of the tube-to-tubesheet welds because they do not meet the criteria established to be considered a RCPB. Therefore, as discussed in item 3.1-1, 025, a plant-specific AMP is not necessary.

3.1.2.2.12. Removed as a Result of LR-ISG-2011-04

As listed in item 3.1-1, 026, This paragraph was removed from NUREG-1800 by LR-ISG-2011-04. In addition, CPNPP has Westinghouse, vs Combustion Engineering, RVI. See FE 3.1.2.2.9 above.

3.1.2.2.13. Removed as a Result of LR-ISG-2011-04

As listed in item 3.1-1, 027, This paragraph was removed from NUREG-1800 by LR-ISG-2011-04. See FE 3.1.2.2.9 above.

3.1.2.2.14. Removed as a Result of LR-ISG-2011-04

As listed in item 3.1-1, 028, CPNPP split pins have been replaced with cold-worked 316 stainless steel. This paragraph was removed from NUREG-1800 by

LR-ISG-2011-04 and replaced by the current 3.1.2.2.9 in SLR-ISG-2021-01-PWRVI. See FE 3.1.2.2.9 above.

3.1.2.2.15. Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2 of this SRP-LR).

QA provisions applicable to LR are discussed in Section B.1.3.

3.1.2.2.16. Ongoing Review of Operating Experience (per LR-ISG-2011-05)

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

The OE process and acceptance criteria are described in Section B.1.4.

3.1.2.3. Time-Limited Aging Analysis

The TLAAs identified below are associated with the Reactor Vessel, Internals, and Reactor Coolant System components:

- Section 4.2, "Reactor Vessel Neutron Embrittlement Analysis"
- Section 4.3, "Metal Fatigue"
- Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses"

3.1.3. Conclusion

The Reactor Vessel, Internals, and Reactor Coolant System piping, fittings, and components that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the Reactor Vessel, Internals, and Reactor Coolant System components are identified in the summaries in Section 3.1.2.1 above.

A description of these AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the PEO.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Reactor Vessel, Internals, and Reactor Coolant System components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the PEO.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 001	High strength, low-alloy steel top head closure stud assembly exposed to air with potential for reactor coolant leakage	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.2. Further evaluation is documented in subsection 3.1.2.2.1.
3.1-1, 002	Nickel alloy tubes and sleeves exposed to reactor coolant and secondary feedwater/steam	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.2 for SG tubes, as well as flow restrictors and feedwater/auxiliary feedwater inlet nozzle dissimilar metal welds (DMWs). Further evaluation is documented in subsection 3.1.2.2.1.
3.1-1, 003	Stainless steel or nickel alloy reactor vessel internal components exposed to reactor coolant and neutron flux	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.5. Further evaluation is documented in subsection 3.1.2.2.1.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 004	Steel pressure vessel support skirt and attachment welds	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Not applicable. The CPNPP reactor vessel is nozzle supported, as described in Section 2.4.1, and does not have a support skirt. The steel support skirt for the Pressurizer and attachment welds are susceptible to cumulative fatigue damage, same as described in item 3.1-1, 009 below.
3.1-1, 005	Steel, stainless steel, or steel (with stainless steel or nickel alloy cladding) steam generator components, pressurizer relief tank components or piping components or bolting	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation (See SRP, Sec 4.3 “Metal Fatigue,” for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Sections 4.3.2 and 4.3.3 for SG components and RCS piping components and bolting. Further evaluation is documented in subsection 3.1.2.2.1.
3.1-1, 006	Not applicable. This line item only applies to BWRs.				
3.1-1, 007	Not applicable. This line item only applies to BWRs.				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 008	Steel (with or without nickel-alloy or stainless steel cladding), or stainless steel; or nickel alloy steam generator components exposed to reactor coolant	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation, and for Class 1 components environmental effects on fatigue are to be addressed. (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.2 for SG components. Further evaluation is documented in subsection 3.1.2.2.1.
3.1-1, 009	Steel (with or without nickel-alloy or stainless steel cladding), stainless steel; nickel alloy RCPB piping; flanges; nozzles & safe ends; pressurizer shell heads & welds; heater sheaths & sleeves; penetrations; thermal sleeves exposed to reactor coolant	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation, and for Class 1 components environmental effects on fatigue are to be addressed. (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.2 for Pressurizer components. Further evaluation is documented in subsection 3.1.2.2.1.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 010	Steel (with or without nickel-alloy or stainless steel cladding), stainless steel; nickel alloy reactor vessel flanges; nozzles; penetrations; pressure housings; safe ends; thermal sleeves; vessel shells, heads and welds exposed to reactor coolant	Cumulative fatigue damage due to fatigue	Fatigue is a TLAA evaluated for the period of extended operation, and for Class 1 components environmental effects on fatigue are to be addressed. (See SRP, Sec 4.3 "Metal Fatigue," for acceptable methods to comply with 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.1.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA in Section 4.3.2. Further evaluation is documented in subsection 3.1.2.2.1.
3.1-1, 011	Not applicable. This line item only applies to BWRs.				
3.1-1, 012	Steel steam generator components: upper and lower shells, transition cone; new transition cone closure weld exposed to secondary feedwater or steam	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD," and Chapter XI.M2, "Water Chemistry," and, for Westinghouse Model 44 and 51 S/G, if corrosion of the shell is found, additional inspection procedures are developed	Yes, detection of aging effects is to be evaluated (See SRP subsection 3.1.2.2.2.1 and 3.1.2.2.2.2)	Consistent with exception to NUREG-1801. Loss of material of steel SG components is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. and ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP. Augmented inspections are not required for CPNPP Delta 76 and D-5 SGs. Further evaluation is documented in subsections 3.1.2.2.2.1 and 3.1.2.2.2.2.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 013	Steel (with or without stainless steel cladding) reactor vessel beltline shell, nozzles, and welds exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement	TLAA is to be evaluated in accordance with Appendix G of 10 CFR Part 50 and RG 1.99. The applicant may choose to demonstrate that the materials of the nozzles are not controlling for the TLAA evaluations	Yes, TLAA (See SRP subsection 3.1.2.2.3.1)	Consistent with NUREG-1801. Loss of fracture toughness is an aging effect assessed by a TLAA in Section 4.2. Further evaluation is documented in subsection 3.1.2.2.3.1.
3.1-1, 014	Steel (with or without cladding) reactor vessel beltline shell, nozzles, and welds; safety injection nozzles	Loss of fracture toughness due to neutron irradiation embrittlement	Chapter XI.M31, “Reactor Vessel Surveillance”	Yes, plant-specific or integrated surveillance program (See SRP subsection 3.1.2.2.3.2)	Consistent with NUREG-1801. Loss of fracture toughness of the steel (with stainless steel cladding) reactor vessel beltline shell, nozzles, and welds in the RV are managed by the Reactor Vessel Surveillance (B.2.3.18) AMP. Further evaluation is documented in subsection 3.1.2.2.3.2.
3.1-1, 015	Stainless steel Babcock & Wilcox (including CASS, martensitic SS, and PH SS) and nickel alloy reactor vessel internal components exposed to reactor coolant and neutron flux	Reduction of ductility and fracture toughness due to neutron irradiation embrittlement, and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement	Ductility -Reduction in fracture toughness is a TLAA to be evaluated for the period of extended operation, See the SRP, Section 4.7, "Other Plant-Specific TLAAs," for acceptable methods of meeting the requirements of 10 CFR 54.21(c).	Yes, TLAA (See SRP subsection 3.1.2.2.3.3)	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant. Further evaluation is documented in subsection 3.1.2.2.3.3.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 016	Not applicable. This line item only applies to BWRs.				
3.1-1, 017	Not applicable. This line item only applies to BWRs.				
3.1-1, 018	Reactor vessel shell fabricated of SA508-Cl 2 forgings clad with stainless steel using a high-heat-input welding process exposed to reactor coolant	Crack growth due to cyclic loading	Growth of intergranular separations is a TLAA evaluated for the period of extended operation. The Standard Review Plan, Section 4.7, “Other Plant-Specific Time-Limited Aging Analysis,” provides guidance for meeting the requirements of 10 CFR 54.21(c).	Yes, TLAA (See SRP subsection 3.1.2.2.5)	Not applicable. CPNPP Units 1 and 2 materials potentially susceptible to underclad cracking were clad using low heat input techniques, which would avoid the formation of underclad cracking. As a result, the underclad cracking TLAA is not applicable to CPNPP Units 1 and 2 for LR as noted in Table 4.1-1. Further evaluation is documented in subsection 3.1.2.2.5.
3.1-1, 019	Stainless steel reactor vessel closure head flange leak detection line and bottom-mounted instrument guide tubes (external to reactor vessel)	Cracking due to stress corrosion cracking	A plant-specific aging management program is to be evaluated	Yes, plant-specific (See SRP subsection 3.1.2.2.6.1)	Consistent with NUREG-1801. Cracking of the stainless steel bottom-mounted instrument guide tubes, seals, and seal table for the RV and reactor vessel flange leak detection components will be managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP. Further evaluation is documented in subsection 3.1.2.2.6.1.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 020	Cast austenitic stainless steel Class 1 piping, piping components, and piping elements exposed to reactor coolant	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry" and, for CASS components that do not meet the NUREG-0313 guidelines, a plant-specific aging management program	Yes, plant-specific (See SRP subsection 3.1.2.2.6.2)	Consistent with exception to NUREG-1801 with an additional AMP to verify effectiveness. Cracking of the CASS Class 1 piping, piping components, and piping elements exposed to reactor coolant will be managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. Additionally, the One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. Further evaluation is documented in subsection 3.1.2.2.6.2
3.1-1, 021	Not applicable. This line item only applies to BWRs.				
3.1-1, 022	Steel steam generator feedwater impingement plate and support exposed to secondary feedwater	Loss of material due to erosion	A plant-specific aging management program is to be evaluated	Yes, plant-specific (See SRP subsection 3.1.2.2.8)	Not applicable. Steam generator feedwater impingement plates and supports are not part of the Unit 1 SGs (model Delta 76) used at CPNPP. The Unit 2 SGs (model D-5) have stainless steel feedwater impingement plates and supports. Further evaluation is documented in subsection 3.1.2.2.8.
3.1-1, 023	[Item 3.1-1, 023 was removed by LR-ISG 2011-04]				
3.1-1, 024	[Item 3.1-1, 024 was removed by LR-ISG 2011-04]				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 025	Steel (with nickel-alloy cladding) or nickel alloy steam generator primary side components: divider plate and tube-to-tube sheet welds exposed to reactor coolant	Cracking due to primary water stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M19, "Steam Generators"	Yes, plant-specific (See SRP subsections 3.1.2.2.11.1 and 3.1.2.2.11.2)	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2016-01 with an additional AMP to verify effectiveness. Cracking of steel (with nickel-alloy cladding) or nickel alloy SG primary side components: divider plate (both units) and tube-to-tubesheet weld (Unit 1 only) exposed to reactor coolant in the RCS will be managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The Steam Generators (B.2.3.10) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. Unit 1 SGs use alloy 690 and do not require an additional inspection or plant-specific program. Unit 2 SGs, which use alloy 600, are bounded under the industry analyses contained in EPRI 3002002850 and do not require an additional inspection or plant-specific program. Additionally, the Unit 2 SGs do not require aging management of the tube-to-tubesheet welds because they do not meet the criteria established to be considered a RCPB. Further evaluation is documented in subsection 3.1.2.2.11.1 and 3.1.2.2.11.2.
3.1-1, 026	[Item 3.1-1, 026 was removed by LR-ISG 2011-04]				
3.1-1, 027	[Item 3.1-1, 027 was removed by LR-ISG 2011-04]				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 028	Westinghouse-specific "Existing Programs" components: Stainless steel, nickel alloy, and X-750 control rod guide tube support pins (split pins) exposed to reactor coolant and neutron flux	Loss of material due to wear; cracking due to SCC, IASCC, fatigue	AMP XI.M16A, "PWR Vessel Internals," and AMP XI.M2, "Water Chemistry" (for SCC mechanisms only)	Yes (See SRP Section 3.1.2.2.9)	Not used. The CPNPP split pins have been replaced with cold-worked 316 stainless steel and, as such, are a No Additional Measures component, consistent with MRP-227, Revision 1-A, and included with item 3.1-1, 055c below. Further evaluation is documented in subsection 3.1.2.2.9.
3.1-1, 029	Not applicable. This line item only applies to BWRs.				
3.1-1, 030	Not applicable. This line item only applies to BWRs.				
3.1-1, 031	Not applicable. This line item only applies to BWRs.				
3.1-1, 032	Deleted by SLR-ISG-2021-01-PWRVI.				
3.1-1, 033	Stainless steel, steel with stainless steel cladding Class 1 reactor coolant pressure boundary components exposed to reactor coolant	Cracking due to stress corrosion cracking	Chapter XI.M1, “ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD” for ASME components, and Chapter XI.M2, “Water Chemistry”	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel and steel with stainless steel cladding Class 1 RCPB components exposed to reactor coolant in the SGs and RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 034	Stainless steel, steel with stainless steel cladding pressurizer relief tank (tank shell and heads, flanges, nozzles) exposed to treated borated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for ASME components, and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel components just outside the ASME Class 1 RCPB and downstream in the RCS exposed to treated borated water >60°C (>140°F) is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.
3.1-1, 035	Stainless steel, steel with stainless steel cladding reactor coolant system cold leg, hot leg, surge line, and spray line piping and fittings exposed to reactor coolant	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components	No	Consistent with NUREG-1801. Cracking of the stainless steel and steel with stainless steel cladding RCS cold leg, hot leg, surge line, and spray line piping and fittings exposed to reactor coolant in the RCS is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 036	Steel, stainless steel pressurizer integral support exposed to air with metal temperature up to 288°C (550°F)	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components	No	Not used. Supports, including supports for Class 1 components such as the Pressurizer, are a commodity addressed in Table 3.5.2-13 below. Aging of these supports is managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP, such as listed for items 3.5-1, 057 and 3.5-1, 091, and Boric Acid Corrosion (B.2.3.4) AMP, as listed for item 3.5-1, 089. Additionally, cracking of Pressurizer components is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP as listed in item 3.1-1, 040 below.
3.1-1, 037	Steel reactor vessel flange	Loss of material due to wear	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components	No	Consistent with NUREG-1801. Loss of material of the steel reactor vessel flange in the RCS is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 038	Cast austenitic stainless steel Class 1 pump casings, and valve bodies and bonnets exposed to reactor coolant >250 deg-C (>482 deg-F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components. For pump casings and valve bodies, screening for susceptibility to thermal aging is not necessary.	No	Consistent with NUREG-1801. Reduction in fracture toughness of the CASS Class 1 pump casings, and valve bodies and bonnets exposed to reactor coolant >250 ºC (>482 ºF) in the RCS is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.
3.1-1, 039	Steel, stainless steel, or steel with stainless steel cladding Class 1 piping, fittings and branch connections < NPS 4 exposed to reactor coolant	Cracking due to stress corrosion cracking, IGSCC (for stainless steel only), and thermal, mechanical, and vibratory loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, Chapter XI.M2, "Water Chemistry," and XI.M35, "One-Time Inspection of ASME Code Class 1 Small-bore Piping"	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel Class 1 piping, fittings, and branch connections < Nominal Pipe Size (NPS) 4 exposed to reactor coolant in the RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP, and the One-Time Inspection of ASME Code Class 1 Small-Bore Piping (B.2.3.21) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 040	Steel with stainless steel or nickel alloy cladding; or stainless steel pressurizer components exposed to reactor coolant	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Cracking of the steel with stainless steel cladding, nickel alloy, or stainless steel pressurizer components exposed to reactor coolant in the RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.
3.1-1, 040.5	Nickel alloy core support pads; core guide lugs exposed to reactor coolant	Cracking due to primary water stress corrosion cracking	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Cracking of the nickel alloy core support pads; core guide lugs exposed to reactor coolant in the RV is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.
3.1-1, 041	Not applicable. This line item only applies to BWRs.				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 042	Steel with stainless steel or nickel alloy cladding or stainless steel primary side components; steam generator upper and lower heads, and tube sheet weld; or pressurizer components exposed to reactor coolant	Cracking due to stress corrosion cracking, primary water stress corrosion cracking	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 1 components, and Chapter XI.M2, "Water Chemistry"	No	Not used. Cracking of steel with stainless steel or nickel alloy cladding or stainless steel primary side components; SG upper and lower heads, and tube sheet weld; or pressurizer components exposed to reactor coolant in the RCS is addressed by items 3.1-1, 018; 3.1-1, 019; 3.1-1, 020; 3.1-1, 025; 3.1-1, 033; 3.1-1, 034; 3.1-1, 035; 3.1-1, 039; 3.1-1, 040; 3.1-1, 046; 3.1-1, 047; 3.1-1, 070; 3.1-1, 071; 3.1-1, 080; and 3.1-1, 082.
3.1-1, 043	Not applicable. This line item only applies to BWRs.				
3.1-1, 044	Steel steam generator secondary manways and handholds (cover only) exposed to air with leaking secondary-side water and/or steam	Loss of material due to erosion	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD" for Class 2 components	No	Consistent with NUREG-1801. Loss of material of the steel SG secondary manways and handholds (cover only) exposed to air with leaking secondary-side water and/or steam in the RCS is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 045	Nickel alloy and steel with nickel-alloy cladding reactor coolant pressure boundary components exposed to reactor coolant	Cracking due to primary water stress corrosion cracking	Chapter XI.M1, "ASME Section XI ISI, IWB, IWC & IWD," and Chapter XI.M2, "Water Chemistry," and, for nickel-alloy, Chapter XI.M11B, "Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-induced Corrosion in Reactor Coolant Pressure Boundary Components (PWRs Only)"	No	Consistent with exception to NUREG-1801. Cracking of the nickel alloy and steel with nickel alloy cladding RCPB components exposed to reactor coolant in the RV, SGs, and RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP and the Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5) AMP.
3.1-1, 046	Stainless steel, nickel-alloy, nickel-alloy welds and/or buttering control rod drive head penetration pressure housing or nozzles safe ends and welds (inlet, outlet, safety injection) exposed to reactor coolant	Cracking due to stress corrosion cracking, primary water stress corrosion cracking	Chapter XI.M1, "ASME Section XI ISI, IWB, IWC & IWD," and Chapter XI.M2, "Water Chemistry," and, for nickel-alloy, Chapter XI.M11B, "Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-induced corrosion in Reactor Coolant Pressure Boundary Components (PWRs Only)"	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel nozzle safe ends and welds (inlet, outlet, SI) exposed to reactor coolant in the RV, as listed in Table 3.1.2-1, is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP and, for the DMWs attaching the carbon steel with stainless steel cladding nozzles to the safe ends, the Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 047	Stainless steel, nickel-alloy control rod drive head penetration pressure housing exposed to reactor coolant	Cracking due to stress corrosion cracking, primary water stress corrosion cracking	Chapter XI.M1, “ASME Section XI ISI, IWB, IWC & IWD,” and Chapter XI.M2, “Water Chemistry”	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel, nickel alloy CRD head penetration pressure housing exposed to reactor coolant, as listed in Table 3.1.2-1, is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP.
3.1-1, 048	Steel external surfaces: reactor vessel top head, reactor vessel bottom head, reactor coolant pressure boundary piping or components adjacent to dissimilar metal (Alloy 82/182) welds exposed to air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, "Boric Acid Corrosion," and Chapter XI.M11B, "Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (PWRs Only)"	No	Consistent with NUREG-1801. Loss of material of the steel external surfaces: reactor vessel closure head, reactor vessel bottom head, reactor vessel and pressurizer nozzles or components adjacent to dissimilar metal (Alloy 82/182) welds exposed to air with borated water leakage in the RV and Pressurizer, as listed in Tables 3.1.2-1 and 3.1.2-3, respectively, is managed by the Boric Acid Corrosion (B.2.3.4) AMP and Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5) AMP.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 049	Steel reactor coolant pressure boundary external surfaces or closure bolting exposed to air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-1801. Loss of material of the steel RCPB external surfaces or closure bolting exposed to air with borated water leakage in the RCS is managed by the Boric Acid Corrosion (B.2.3.4) AMP.
3.1-1, 050	Cast austenitic stainless steel Class 1 piping, piping component, and piping elements and control rod drive pressure housings exposed to reactor coolant >250 deg-C (>482 deg-F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M12, "Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (CASS)"	No	Consistent with NUREG-1801. Reduction of fracture toughness of the CASS Class 1 piping, piping component (Unit 1 elbows) exposed to reactor coolant >250 °C (>482 °F) in the RCS is managed by the Thermal Aging Embrittlement of Cast Austenitic Stainless Steel (B.2.3.6) AMP. The CRD pressure housings are made of stainless steel, not CASS.
3.1-1, 051a	Stainless steel or nickel alloy Babcock & Wilcox reactor internal “Primary” components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, irradiation-assisted stress corrosion cracking, or fatigue	Chapter XI.M16A, “PWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry” (for SCC mechanisms only)	No	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 051b	Stainless steel or nickel alloy Babcock & Wilcox reactor internal "Expansion" components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, irradiation-assisted stress corrosion cracking, fatigue, or overload	Chapter XI.M16A, "PWR Vessel Internals," and Chapter XI.M2, "Water Chemistry" (for SCC mechanisms only)	No	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant.
3.1-1, 052a	Stainless steel or nickel alloy Combustion Engineering reactor internal "Primary" components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, irradiation-assisted stress corrosion cracking, or fatigue	Chapter XI.M16A, "PWR Vessel Internals," and Chapter XI.M2, "Water Chemistry" (for SCC mechanisms only)	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.
3.1-1, 052b	Stainless steel or nickel alloy Combustion Engineering reactor internal "Expansion" components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, irradiation-assisted stress corrosion cracking, or fatigue	Chapter XI.M16A, "PWR Vessel Internals," and Chapter XI.M2, "Water Chemistry" (for SCC mechanisms only)	No	Not applicable. CPNPP is a Westinghouse plant, not a Combustion Engineering plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 052c	Stainless steel or nickel alloy Combustion Engineering reactor internal “Existing Programs” components exposed to reactor coolant and neutron flux	Cracking due to stress corrosion cracking, irradiation-assisted stress corrosion cracking, or fatigue	Chapter XI.M16A, “PWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry” (for SCC mechanisms only)	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.
3.1-1, 053a	Stainless steel or nickel alloy Westinghouse reactor internal “Primary” components exposed to reactor coolant and neutron flux	Cracking due to SCC, IASCC, fatigue	Chapter XI.M16A, “PWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry” (for SCC mechanisms only)	Yes (Section 3.1.2.2.9)	Consistent with exception to NUREG-1801 as updated by SLR-ISG-2021-01-PWRVI. Cracking of the stainless steel or nickel alloy Westinghouse reactor internal "Primary" components exposed to reactor coolant, neutron flux will be managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 053b	Stainless steel Westinghouse reactor internal “Expansion” components exposed to reactor coolant and neutron flux	Cracking due to SCC, IASCC, fatigue	Chapter XI.M16A, “PWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry” (for SCC mechanisms only)	Yes (Section 3.1.2.2.9)	Consistent with exception to NUREG-1801 as updated by SLR-ISG-2021-01-PWRVI. Cracking of the stainless steel Westinghouse reactor internal "Expansion" components exposed to reactor coolant and neutron flux will be managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.
3.1-1, 053c	Stainless steel, nickel alloy, or stellite Westinghouse reactor internal "Existing Programs" components exposed to reactor coolant, neutron flux	Cracking due to SCC, IASCC, fatigue	Chapter XI.M16A, “PWR Vessel Internals,” and Chapter XI.M2, “Water Chemistry” (for SCC mechanisms only)	Yes (Section 3.1.2.2.9)	Consistent with exception to NUREG-1801 as updated by SLR-ISG-2021-01-PWRVI. Cracking of the stainless steel, nickel alloy Westinghouse reactor internal "Existing Programs" components exposed to reactor coolant; neutron flux is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 054	Stainless steel Westinghouse-design bottom mounted instrument system flux thimble tubes (with or without chrome plating) exposed to reactor coolant and neutron flux (Westinghouse “Existing Programs” components)	Loss of material due to wear	Chapter XI.M16A, “PWR Vessel Internals,” or Chapter XI.M37, "Flux Thimble Tube Inspection"	No	Consistent with NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Loss of material of the stainless steel bottom mounted instrument system flux thimble tubes exposed to reactor coolant and neutron flux is managed by the Flux Thimble Tube Inspection (B.2.3.23) AMP.
3.1-1, 055a	Stainless steel or nickel alloy Babcock and Wilcox reactor internal “No Additional Measures” components exposed to reactor coolant and neutron flux	No additional aging management for reactor internal “No Additional Measures” components unless required by ASME Section XI, Examination Category B-N-3 or relevant operating experience invalidates MRP-227-A.	Chapter XI.M16A, “PWR Vessel Internals”	No	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 055b	Stainless steel or nickel alloy Combustion Engineering reactor internal “No Additional Measures” components exposed to reactor coolant and neutron flux	No additional aging management for reactor internal “No Additional Measures” components unless required by ASME Section XI, Examination Category B-N-3 or relevant operating experience invalidates MRP-227-A.	Chapter XI.M16A, “PWR Vessel Internals”	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.
3.1-1, 055c	Stainless steel or nickel alloy Westinghouse reactor internal “No Additional Measures” components exposed to reactor coolant and neutron flux	No additional aging management for reactor internal "No Additional Measures" components unless required by ASME Section XI, Examination Category B-N-3 or relevant operating experience exists	Chapter XI.M16A, “PWR Vessel Internals”	Yes (Section 3.1.2.2.9)	Consistent with NUREG-1801 as supplemented by LR-ISG-2011-04 (in NUREG-2191 but not SLR-ISG-2021-01-PWRVI). The stainless steel “No Additional Measures” components exposed to reactor coolant and neutron flux in the RV internals are managed by the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 056a	Stainless steel (SS, including CASS, PH SS or martensitic SS) or nickel alloy Combustion Engineering reactor internal “Primary” components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, “PWR Vessel Internals”	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 056b	Stainless steel (SS, including CASS, PH SS or martensitic SS) Combustion Engineering "Expansion" reactor internal components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, "PWR Vessel Internals"	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 056c	Stainless steel (SS, including CASS, PH SS or martensitic SS) or nickel alloy Combustion Engineering reactor internal "Existing Programs" components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, "PWR Vessel Internals"	No	Not applicable. CPNPP is a Westinghouse plant, not a CE plant.
3.1-1, 057	[There is no 3.1-1, 057 in NUREG-1800 or SLR-ISG-2021-01-PWRVI.]				
3.1-1, 058a	Stainless steel (SS, including CASS, PH SS or martensitic SS) or nickel alloy Babcock & Wilcox reactor internal "Primary" components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to wear; or loss of material due to wear	Chapter XI.M16A, "PWR Vessel Internals"	No	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 058b	Stainless steel (SS, including CASS, PH SS or martensitic SS) or nickel alloy Babcock & Wilcox reactor internal "Expansion" components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, "PWR Vessel Internals"	No	Not applicable. CPNPP is a Westinghouse plant, not a Babcock & Wilcox plant.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 059a	Stainless steel (SS, including CASS, PH SS or martensitic SS) or nickel alloy Westinghouse reactor internal “Primary” components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, “PWR Vessel Internals”	Yes (Section 3.1.2.2.9)	Consistent with NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Loss of fracture toughness, changes in dimensions, loss of preload, and loss of material of the stainless steel or nickel alloy Westinghouse reactor internal “Primary” components exposed to reactor coolant and neutron flux is managed by the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 059b	Stainless steel (SS, including CASS, PH SS or martensitic SS) Westinghouse reactor internal "Expansion" components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; or changes in dimensions due to void swelling or distortion; or loss of preload due to thermal and irradiation enhanced stress relaxation or creep; or loss of material due to wear	Chapter XI.M16A, "PWR Vessel Internals"	Yes (Section 3.1.2.2.9)	Consistent with NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Loss of fracture toughness, changes in dimensions, loss of preload, and loss of material of the stainless steel Westinghouse reactor internal "Expansion" components exposed to reactor coolant and neutron flux is managed by the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 059c	Stainless steel (SS, including CASS, PH SS or martensitic SS), nickel alloy, or stellite Westinghouse reactor internal “Existing Programs” components exposed to reactor coolant and neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement and for CASS, martensitic SS, and PH SS due to thermal aging embrittlement; changes in dimensions due to void swelling, distortion; loss of preload due to thermal and irradiation- enhanced stress relaxation, creep; loss of material due to wear	AMP XI.M16A, "PWR Vessel Internals"	Yes (Section 3.1.2.2.9)	Consistent with NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Loss of fracture toughness, changes in dimensions, loss of preload, and loss of material of the stainless steel or nickel alloy, Westinghouse reactor internal “Existing Programs” components exposed to reactor coolant and neutron flux is managed by the PWR Vessel Internals (B.2.3.7) AMP. Further evaluation is documented in subsection 3.1.2.2.9.
3.1-1, 060	Not applicable. This line item only applies to BWRs.				
3.1-1, 061	Steel steam generator steam nozzle and safe end, feedwater nozzle and safe end, AFW nozzles and safe ends exposed to secondary feedwater/steam	Wall thinning due to flow-accelerated corrosion	Chapter XI.M17, “Flow-Accelerated Corrosion”	No	Consistent with exception to NUREG-1801. Wall thinning of the steel SG MS nozzle, feedwater nozzle, and AFW nozzle exposed to secondary feedwater/steam is managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 062	High-strength, low alloy steel, or stainless steel closure bolting; stainless steel control rod drive head penetration flange bolting exposed to air with reactor coolant leakage	Cracking due to stress corrosion cracking	Chapter XI.M18, "Bolting Integrity"	No	Not used. There are no high-strength closure bolting exposed to air with reactor coolant leakage other than the reactor head closure studs addressed in item 3.1-1, 092 below. The CRD head penetrations are welded, not bolted.
3.1-1, 063	Not applicable. This line item only applies to BWRs.				
3.1-1, 064	Steel closure bolting exposed to air – indoor uncontrolled	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of material of the steel closure bolting exposed to air – indoor uncontrolled in the SGs and RCS is managed by the Bolting Integrity (B.2.3.9) AMP.
3.1-1, 065	Stainless steel control rod drive head penetration flange bolting exposed to air with reactor coolant leakage	Loss of material due to wear	Chapter XI.M18, "Bolting Integrity"	No	Not used. Loss of material for stainless steel closure bolting in the RCS is included with item 3.2-1, 013 below. A generic note C is used. Furthermore, the CRD head penetrations are welded, not bolted.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 066	High-strength, low alloy steel, or stainless steel closure bolting; stainless steel control rod drive head penetration flange bolting exposed to air with reactor coolant leakage	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of preload of the low alloy steel or stainless steel RCS closure bolting exposed to air – indoor controlled, with potential for reactor coolant leakage is managed by the Bolting Integrity (B.2.3.9) AMP. The CRD head penetrations are welded, not bolted.
3.1-1, 067	Steel or stainless steel closure bolting exposed to air – indoor with potential for reactor coolant leakage	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of preload of the steel closure bolting exposed to air – indoor uncontrolled with potential for reactor coolant leakage in the SGs is managed by the Bolting Integrity (B.2.3.9) AMP. Loss of preload of the stainless steel closure bolting exposed to air – indoor with potential for reactor coolant leakage in the RCS is addressed by item 3.1-1, 066.
3.1-1, 068	Nickel alloy steam generator tubes exposed to secondary feedwater or steam	Changes in dimension ("denting") due to corrosion of carbon steel tube support plate	Chapter XI.M19, “Steam Generators,” and Chapter XI.M2, “Water Chemistry”	No	Not used. The nickel alloy SG tubes exposed to secondary feedwater or steam has a stainless steel tube support plate. Furthermore, loss of material due to wear or fretting is addressed in item 3.1-1, 077 below.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 069	Nickel alloy steam generator tubes and sleeves exposed to secondary feedwater or steam	Cracking due to outer diameter stress corrosion cracking and intergranular attack	Chapter XI.M19, “Steam Generators,” and Chapter XI.M2, “Water Chemistry”	No	Consistent with exception to NUREG-1801. Cracking of the nickel alloy SG tubes and sleeves exposed to secondary feedwater is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801.
3.1-1, 070	Nickel alloy steam generator tubes, repair sleeves, and tube plugs exposed to reactor coolant	Cracking due to primary water stress corrosion cracking	Chapter XI.M19, “Steam Generators,” and Chapter XI.M2, “Water Chemistry”	No	Consistent with exception to NUREG-1801. Cracking of the nickel alloy SG tubes, repair sleeves, and tube plugs exposed to reactor coolant is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 071	Steel, chrome plated steel, stainless steel, nickel alloy steam generator U-bend supports including anti-vibration bars exposed to secondary feedwater or steam	Cracking due to stress corrosion cracking or other mechanism(s); loss of material due general (steel only), pitting, and crevice corrosion	Chapter XI.M19, "Steam Generators," and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Cracking and loss of material of the steel, stainless steel, and nickel alloy SG anti-vibration bars, internal discharge piping, Unit 1 feedwater distribution ring, Unit 1 spray nozzle, Unit 2 preheater assembly, as well as tube support plates and tubes exposed to secondary feedwater or steam are managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801. Some of the nickel alloy anti-vibration bars are chrome-plated.
3.1-1, 072	Steel steam generator tube support plate, tube bundle wrapper, supports and mounting hardware exposed to secondary feedwater or steam	Loss of material due to erosion, general, pitting, and crevice corrosion, ligament cracking due to corrosion	Chapter XI.M19, "Steam Generators," and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Loss of material of the steel SG tube wrapper, steam separator assembly, and tubesheet exposed to secondary feedwater or steam is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801. The SG tube support plate is stainless steel and is addressed by item 3.1-1, 071.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 073	Nickel alloy steam generator tubes and sleeves exposed to phosphate chemistry in secondary feedwater or steam	Loss of material due to wastage and pitting corrosion	Chapter XI.M19, "Steam Generators," and Chapter XI.M2, "Water Chemistry"	No	Not applicable. Nickel alloy SG tubes and sleeves are not exposed to phosphate chemistry in secondary feedwater or steam.
3.1-1, 074	Steel steam generator upper assembly and separators including feedwater inlet ring and support exposed to secondary feedwater or steam	Wall thinning due to flow-accelerated corrosion	Chapter XI.M19, "Steam Generators," and Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Wall thinning of the steel steam separator assembly exposed to secondary feedwater or steam is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801.
3.1-1, 075	Steel steam generator tube support lattice bars exposed to secondary feedwater or steam	Wall thinning due to flow-accelerated corrosion and general corrosion	Chapter XI.M19, "Steam Generators," and Chapter XI.M2, "Water Chemistry"	No	Not applicable. There are no steel SG tube support lattice bars exposed to secondary feedwater or steam.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 076	Steel, chrome plated steel, stainless steel, nickel alloy steam generator U-bend supports including anti-vibration bars exposed to secondary feedwater or steam	Loss of material due to fretting	Chapter XI.M19, “Steam Generators”	No	Consistent with exception to NUREG-1801. Loss of material of the stainless steel and nickel alloy SG anti-vibration bars exposed to secondary feedwater or steam is managed by the Steam Generators (B.2.3.10) AMP, which takes exception to NUREG-1801. There are no chrome plated steel SG anti-vibration bars exposed to secondary feedwater or steam. Some of the nickel alloy anti-vibration bars are chrome-plated.
3.1-1, 077	Nickel alloy steam generator tubes and sleeves exposed to secondary feedwater or steam	Loss of material due to wear and fretting	Chapter XI.M19, “Steam Generators”	No	Consistent with exception to NUREG-1801. Loss of material of the nickel alloy SG tubes and sleeves exposed to secondary feedwater or steam in the RCS is managed by the Steam Generators (B.2.3.10) AMP, which takes exception to NUREG-1801.
3.1-1, 078	Nickel alloy steam generator components such as, secondary side nozzles (vent, drain, and instrumentation) exposed to secondary feedwater or steam	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection," or Chapter XI.M1, “ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD.”	No	Consistent with exception to NUREG-1801. Cracking of the nickel alloy SG nozzle DMWs, thermal sleeves, and flow restrictors exposed to secondary feedwater or steam is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 079	Not applicable. This line item only applies to BWRs.				
3.1-1, 080	Stainless steel or steel with stainless steel cladding pressurizer relief tank: tank shell and heads, flanges, nozzles (none-ASME Section XI components) exposed to treated borated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel non-ASME Section XI components listed in Table 3.1.2-3 exposed to reactor coolant / treated borated water >60°C (>140°F) is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. There are no steel with stainless steel cladding non-ASME Section XI components exposed to treated borated water >60°C (>140°F) in the RCS. Furthermore, the PRT temperature is maintained and not exposed to temperatures > 60°C (> 140°F) and included with item 3.2-1, 018 below.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 081	Stainless steel pressurizer spray head exposed to reactor coolant	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Cracking of the stainless steel pressurizer spray head and pressurizer sleeve exposed to reactor coolant in the RV, internals, and RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking.
3.1-1, 082	Nickel alloy pressurizer spray head exposed to reactor coolant	Cracking due to stress corrosion cracking, primary water stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. The pressurizer spray head is made of stainless steel and is addressed by item 3.1-1, 081.
3.1-1, 083	Steel steam generator shell assembly exposed to secondary feedwater or steam	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Loss of material of the steel SG shell assembly exposed to secondary feedwater or steam is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material.
3.1-1, 084	Not applicable. This line item only applies to BWRs.				
3.1-1, 085	Not applicable. This line item only applies to BWRs.				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 086	Stainless steel steam generator primary side divider plate exposed to reactor coolant	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry"	No	Not applicable. The SG primary side divider plate exposed to reactor coolant is made of nickel alloy and is addressed by item 3.1-1, 025 for cracking.
3.1-1, 087	Stainless steel or nickel-alloy PWR reactor internal components exposed to reactor coolant and neutron flux	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Loss of material of the stainless steel or nickel alloy reactor internal components exposed to reactor coolant and neutron flux is managed by the Water Chemistry (B.2.3.2) AMP, which includes an exception to NUREG-1801.
3.1-1, 088	Stainless steel; steel with nickel-alloy or stainless steel cladding; and nickel-alloy reactor coolant pressure boundary components exposed to reactor coolant	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry"	No	Consistent with exception to NUREG-1801. Loss of material of the stainless steel; steel with nickel-alloy or stainless steel cladding; and nickel-alloy RCPB components exposed to reactor coolant in the RCS is managed by the Water Chemistry (B.2.3.2) AMP, which includes an exception to NUREG-1801.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 089	Steel piping, piping components, and piping elements exposed to closed cycle cooling water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of steel RCP bearing oil cooler channel head exposed to closed cycle cooling water in the RCS is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. A generic note D is used.
3.1-1, 090	Copper alloy piping, piping components, and piping elements exposed to closed cycle cooling water	Loss of material due to pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of copper alloy RCP bearing oil cooler tubes and tubesheet exposed to closed cycle cooling water in the RCS is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. A generic note D is used.
3.1-1, 091	Not applicable. This line item only applies to BWRs.				
3.1-1, 092	High-strength low alloy steel closure head stud assembly exposed to air with potential for reactor coolant leakage	Cracking due to stress corrosion cracking; loss of material due to general, pitting, and crevice corrosion, or wear (PWR)	Chapter XI.M3, “Reactor Head Closure Stud Bolting”	No	Consistent with exception to NUREG-1801. Cracking and loss of material of the steel closure head stud assembly exposed to air – indoor uncontrolled, with potential for reactor coolant leakage, in the RCS are managed by the Reactor Head Closure Stud Bolting (B.2.3.3) AMP, which includes an exception to NUREG-1801. Some of the reactor head closure studs may be high-strength. A plant-specific note is used in Table 3.1.2-1.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 093	Copper alloy >15% Zn or >8% Al piping, piping components, and piping elements exposed to closed cycle cooling water	Loss of material due to selective leaching	Chapter XI.M33, "Selective Leaching "	No	Not applicable. The copper alloy piping components (RCP bearing oil cooler tubes and tubesheet) exposed to closed cycle cooling water in the RCS do not have >15% Zn or >8% Al.
3.1-1, 094	Not applicable. This line item only applies to BWRs.				
3.1-1, 095	Not applicable. This line item only applies to BWRs.				
3.1-1, 096	Not applicable. This line item only applies to BWRs.				
3.1-1, 097	Not applicable. This line item only applies to BWRs.				
3.1-1, 098	Not applicable. This line item only applies to BWRs.				
3.1-1, 099	Not applicable. This line item only applies to BWRs.				
3.1-1, 100	Not applicable. This line item only applies to BWRs.				
3.1-1, 101	Not applicable. This line item only applies to BWRs.				
3.1-1, 102	Not applicable. This line item only applies to BWRs.				
3.1-1, 103	Not applicable. This line item only applies to BWRs.				
3.1-1, 104	Not applicable. This line item only applies to BWRs.				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 105	Steel piping, piping components and piping element exposed to concrete	None	None, provided 1) attributes of the concrete are consistent with American Concrete Institute (ACI) 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. There are no steel piping, piping components and piping element exposed to concrete in the RCS.
3.1-1, 106	Nickel alloy piping, piping components and piping element exposed to air – indoor, uncontrolled, or air with borated water leakage	None	None	NA -No AEM or AMP	Consistent with NUREG-1801.
3.1-1, 107	Stainless steel piping, piping components and piping element exposed to gas, concrete, air with borated water leakage, air – indoors, uncontrolled	None	None	NA -No AEM or AMP	Consistent with NUREG-1801.
3.1-1, 108	[There is no item 108 in Table 3.1-1 of NUREG-1800]				
3.1-1, 109	[There is no item 109 in Table 3.1-1 of NUREG-1800]				

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.1-1, 110	Not applicable. This line item, added by LR-ISG-2012-01 (wall thinning due to erosion) only applies to BWRs.				
3.1-1, 114	Reactor coolant system components defined as ASME Section XI Code Class components (ASME Code Class 1 reactor coolant pressure boundary components, reactor vessel interior attachments, or core support structure components; or ASME Class 2 and 3 components – including ASME defined appurtenances, component supports, and associated pressure boundary welds, or components subject to plant-specific equivalent classifications for these ASME code classes)	Cracking due to SCC, IGSCC, PWSCC, IASCC (SCC mechanisms for stainless steel, nickel alloy components only), fatigue, or cyclic loading; loss of material due to general corrosion (steel only), pitting corrosion, crevice corrosion, or wear	AMP XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD," and AMP XI.M2, "Water Chemistry" (water chemistry-related or corrosion-related aging effect mechanisms only)	No	Consistent with exception to NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Cracking and loss of material of RCS components defined as ASME Section XI Code Class components (Category B-N-3) is managed by the ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP and Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 118	Stainless steel, nickel alloy PWR reactor vessel internal components or LRA/SLRA-specified reactor vessel internal component exposed to reactor coolant, neutron flux	Cracking due to SCC, IASCC, cyclic loading, fatigue	Plant-specific aging management program or AMP XI.M16A, "PWR Vessel Internals," and AMP XI.M2, "Water Chemistry" (SCC and IASCC only), with an adjusted site-specific or component-specific aging management basis for a specified reactor vessel internal component	Yes (Section 3.1.2.2.9)	Not used. Cracking of stainless steel, nickel alloy PWR reactor vessel internal components or LRA-specified reactor vessel internal component exposed to reactor coolant, neutron flux is addressed in items 3.1-1, 028; 3.1-1, 053a; 3.1-1, 053b; and 3.1-1, 053c. Further evaluation is documented in subsection 3.1.2.2.9.
3.1-1, 119	Stainless steel, nickel alloy, stellite PWR reactor vessel internal components or LRA/SLRA specified reactor vessel internal component exposed to reactor coolant, neutron flux	Loss of fracture toughness due to neutron irradiation embrittlement or thermal aging embrittlement; changes in dimensions due to void swelling or distortion; loss of preload due to thermal and irradiation-enhanced stress relaxation or creep; loss of material due to wear	Plant-specific aging management program or AMP XI.M16A, "PWR Vessel Internals," with an adjusted site-specific or component-specific aging management basis for a specified reactor vessel internal component	Yes (Section 3.1.2.2.9)	Consistent with NUREG-1801 as supplemented by SLR-ISG-2021-01-PWRVI. Loss of fracture toughness and changes in dimensions of the stainless steel BMI: flux thimble tubes exposed to reactor coolant and neutron flux is managed by the PWR Vessel Internals (B.2.3.7) AMP. A plant-specific note is used. Loss of preload is not applicable to these components and loss of material is addressed by item 3.1-1, 054 above. Further evaluation is documented in subsection 3.1.2.2.9.

Table 3.1-1: Summary of Aging Management Programs for Reactor Vessel, Internals, and Reactor Coolant System					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.1-1, 127a	Steel (with stainless steel or nickel alloy cladding) steam generator heads and tubesheets exposed to reactor coolant	Loss of material due to boric acid corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M19, “Steam Generators”	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2016-01. Loss of material of the steel with stainless steel or nickel alloy cladding SG heads and tubesheets exposed to reactor coolant in the RCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801, and the Steam Generators (B.2.3.10) AMP, which also takes exception to NUREG-1801.

Table 3.1.2-1: Reactor Pressure Vessel – Summary of Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect Requiring Management	Aging Management Programs	NUREG-1801 Item	Table 1 Item	Notes
Bottom head (dome, torus, and welds)	Pressure boundary	Carbon steel with stainless steel cladding	Air - indoor uncontrolled (external)	Loss of material	Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5)	IV.A2.RP-379	3.1-1, 048	A
Bottom head (dome, torus, and welds)	Pressure boundary	Carbon steel with stainless steel cladding	Air with borated water leakage (external)	Loss of material	Boric Acid Corrosion (B.2.3.4)	IV.A2.RP-379	3.1-1, 048	A
Bottom head (dome, torus, and welds)	Pressure boundary	Carbon steel with stainless steel cladding	Reactor coolant (internal)	Loss of material	Water Chemistry (B.2.3.2)	IV.A2.RP-28	3.1-1, 088	B
Bottom head penetrations (flux thimble tubing)	Pressure boundary	Stainless steel	Reactor coolant (external)	Cracking	ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1)	IV.A2.RP-154	3.1-1, 019	E, 1
Bottom head penetrations (flux thimble tubing)	Pressure boundary	Stainless steel	Reactor coolant (external)	Loss of material	Water Chemistry (B.2.3.2)	IV.A2.RP-28	3.1-1, 088	D
Bottom head penetrations (flux thimble tubing)	Pressure boundary	Stainless steel	Reactor coolant (external)	Loss of material - wear	Flux Thimble Tube Inspection (B.2.3.23)	IV.B2.RP-284	3.1-1, 054	A, 1
Bottom head penetrations (guide tubes, seals)	Pressure boundary	Stainless steel	Air - indoor uncontrolled (external)	None	None	IV.E.RP-04	3.1-1, 107	C
Bottom head penetrations (flux thimble tubing)	Pressure boundary	Stainless steel	Reactor coolant (external)	Cracking	Water Chemistry (B.2.3.2)	IV.A2.RP-154	3.1-1, 019	E, 1

Vessel shell (lower shell plates, circumferential and longitudinal welds)	Pressure boundary	Carbon steel with stainless steel cladding	Reactor coolant and neutron flux (internal)	Reduction in fracture toughness	TLAA (Section 4.2)	IV.A2.R-84	3.1-1, 013	A
Vessel shell (upper shell plates, circumferential and longitudinal welds)	Pressure boundary	Carbon steel with stainless steel cladding	Air with borated water leakage (external)	Loss of material	Boric Acid Corrosion (B.2.3.4)	IV.A2.R-17	3.1-1, 049	A
Vessel shell (upper shell plates, circumferential and longitudinal welds)	Pressure boundary	Carbon steel with stainless steel cladding	Reactor coolant (internal)	Loss of material	Water Chemistry (B.2.3.2)	IV.A2-RP-28	3.1-1, 088	B

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. Thimble tubing is exposed externally to reactor coolant downstream of the seal at the bottom head penetration and with potential leakage past the seal into the guide tube. Likewise, the guide tubes and seal table only contain treated borated water (reactor coolant) with leakage past the seal.

2. Only select reactor head closure studs, nuts and washers are considered high strength (yield strength ≥ 150 kilo pounds per square inch (ksi)) (FSAR Tables 5.3-4A, 5.3-4B, and 5.3-4C) and susceptible to cracking.

3. Based on the OE reflected in NUREG-2191 (IV.A2.R-414) and NUREG-2192 (3.1-1, 117), loss of material due to wear can occur in the stainless steel thermal sleeves of PWR CRD head penetration nozzles due to interaction between the nozzle and the thermal sleeve. This SLR OE recommends the use of a plant-specific AMP to manage this aging effect; as such, the ASME Section XI, Subsection IWB, IWC, and IWD (B.2.3.1) AMP includes inspection for the loss of material due to wear of the CRDM thermal sleeves.

4. The Material Stress Improvement Process (MSIP) has been completed for Unit 1 inlet and outlet nozzle welds and some Unit 2 inlet and outlet nozzle welds. As such, these nozzle to safe end welds are less susceptible to cracking due to PWSCC, which is managed by the Cracking of Nickel-Alloy Components and Loss of Material Due to Boric Acid-Induced Corrosion in Reactor Coolant Pressure Boundary Components (B.2.3.5) AMP.

Table 3.1.2-2: Reactor Vessel Internals – Summary of Aging Management Evaluation

Component Type	Intended Function (IF)	Material	Environment	Aging Effect Requiring Management	Aging Management Program	NUREG-1801 Item	Table 1 Item	Notes

Component Type	Intended Function (IF)	Material	Environment	Aging Effect Requiring Management	Aging Management Program	NUREG-1801 Item	Table 1 Item	Notes
Upper internals assembly: upper core plate	Flow distribution	Stainless steel	Reactor coolant and neutron flux	Loss of material	PWR Vessel Internals (B.2.3.7)	IV.B2.RP-290b	3.1-1, 059b	A
Upper internals assembly: upper core plate	Structural support	Stainless steel	Reactor coolant and neutron flux	Cracking	PWR Vessel Internals (B.2.3.7)	IV.B2.RP-291b	3.1-1, 053b	A
Upper internals assembly: upper core plate	Structural support	Stainless steel	Reactor coolant and neutron flux	Cracking	Water Chemistry (B.2.3.2)	IV.B2.RP-291b	3.1-1, 053b	B
Upper internals assembly: upper core plate	Structural support	Stainless steel	Reactor coolant and neutron flux	Loss of fracture toughness	PWR Vessel Internals (B.2.3.7)	IV.B2.RP-290b	3.1-1, 059b	A
Upper internals assembly: upper core plate	Structural support	Stainless steel	Reactor coolant and neutron flux	Loss of material	PWR Vessel Internals (B.2.3.7)	IV.B2.RP-290b	3.1-1, 059b	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. The PWR Vessel Internals (B.2.3.7) Program manages change in dimension and loss of fracture toughness for stainless steel flux thimble tubes. Loss of preload is not applicable to flux thimble tubes, and loss of material is addressed by NUREG-1801 item IV.B2.RP-284. Flux thimble tubes are existing program components.

2. The annular thermal shields for both units have been replaced with neutron shielding panels.

3. There are three incore flux thimble tubes plugged in Unit 2. Flux thimble tube plugs are no additional measures components.

4. Denotes a new line item added by SLR-ISG-2021-01-PWRVI, not previously captured in NUREG-1801, including corresponding LR-ISGs, and NUREG-2191.

5. Core barrel, LCP, lower support column, lower support plate, and upper core plate have an existing fatigue analysis as described in Section 4.3.5.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG 1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 for material, environment, and aging effect but a different AMP is credited.

H. Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

1. Per Section 3.1.2.2.6.2, the One-Time Inspection will include detection of cracking for CASS exposed to reactor coolant and will be based on screening for carbon and ferrite content.
2. Piping downstream of closed isolation valves are empty during normal operation and contain the same internal and external environment.
3. Orifices/scoops for transition from Class 1 to Class 2 include small-bore socket welds.
4. Thermal sleeves are inserted in the Pressurizer spray and surge line nozzles per FSAR Sections 5.4.10.2.2 and 5.4.3.4.
5. With natural circulation considerations, RCPs are not required for accident mitigation; therefore, RCP coolers are subject to AMR as part of the CCW pressure boundary (tubes/coils, tube sheets and channel heads) or as a leakage boundary (shells).
6. Each RCP oil system includes an elastomer seal on the upper oil reservoir and on the lower oil reservoir.
7. Though not in NUREG-1801 Rev 2, OE reflected in NUREG-2191 item VII.H2.A-677 indicates that elastomer degradation could conservatively occur with prolonged exposure to lubricating oil.
8. PRT temperature is limited to no greater than 113ºF by standard operating procedure; therefore, the relief tank is not susceptible to SCC.
9. Cracking of the vessel flange leak detection components is managed by the ASME Section XI Inservice Inspections, Subsection IWB, IWC, and IWD (B.2.3.1) AMP and Water Chemistry (B.2.3.2) AMP.
10. SWOL of the Alloy 82/182 (600) with Alloy 52/52M (690) has been performed for both the Unit 1 and 2 pressurizer surge line, spray line, PORV line, and the three safety relief lines, at the DMWs between the nozzles and piping. As such, the Alloy 690 SWOLs serve as the pressure boundary and the base Alloy 600 weld is removed from the scope of LR.
11. Pressurizer safety and relief valve inlet line piping has an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4.
12. Structural support functions of Class 1 moment restraints are managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP and evaluated in Table 3.5.2-1.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG 1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 for material, environment, and aging effect but a different AMP is credited.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. The carbon steel components of the SGs, including the shell, nozzles, taps, and manways, have an external temperature greater than 212°F and are at a higher temperature than the air-indoor uncontrolled and air with borated water leakage environment. Therefore, condensation and moisture accumulation will not occur and loss of material due to general, pitting, and crevice corrosion does not apply.

2. The aging effect and mechanism of reduction of heat transfer due to fouling is not in NUREG-1801 for this component, material, and environment; however, it is applicable to this combination. Based on OE reflected in NUREG-2191 (IV.D1.R-407), the Water Chemistry (B.2.3.2) AMP and Steam Generators (B.2.3.10) AMP are used to manage the aging effects for this component, material, and environment combination.

3. Unit 2 SG tube-to-tubesheet welds are not required to maintain the RCPB as per permanent alternate repair criterion H* (Reference ML12263A036).

3.2. AGING MANAGEMENT OF ENGINEERED SAFETY FEATURES

3.2.1. Introduction

This section provides the results of the AMR for those components identified in Section 2.3.2, "Engineered Safety Features", as being subject to AMR. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Combustible Gas Control System (2.3.2.1)
- Containment Isolation System (2.3.2.2)
- Containment Spray System (2.3.2.3)
- Residual Heat Removal System (2.3.2.4)
- Safety Injection System (2.3.2.5)

Note – Habitability and filtration engineered safety features are addressed in Section 3.3.2 with other auxiliary plant ventilation systems.

3.2.2. Results

The following tables summarize the results of the AMR for ESF Systems.

Table 3.2.2-1: Combustible Gas Control System - Summary of Aging Management Evaluation

Table 3.2.2-2: Containment Isolation System - Summary of Aging Management Evaluation

Table 3.2.2-3: Containment Spray System - Summary of Aging Management Evaluation

Table 3.2.2-4: Residual Heat Removal System - Summary of Aging Management Evaluation[1]

Table 3.2.2-5: Safety Injection System - Summary of Aging Management Evaluation[2]

[1] See Table 3.1.2-3 for portions of the RHRS included in the RCPB (ASME Class 1).
[2] See Table 3.1.2-3 for portions of the SIS included in the RCPB (ASME Class 1).

3.2.2.1. Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.2.2.1.1. Combustible Gas Control System

Materials

The materials of construction for the CGCS components are:

- Carbon steel
- Stainless steel

Environments

The CGCS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage

Aging Effects Requiring Management

The following aging effects associated with the CGCS require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the CGCS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

3.2.2.1.2. Containment Isolation System

Materials

The materials of construction for the CIS components are:

- Carbon steel
- Stainless steel

Environments

The CIS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Lubricating oil

Aging Effects Requiring Management

The following aging effects associated with the CIS require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the CIS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)

3.2.2.1.3. Containment Spray System

Materials

The materials of construction for the CSS components are:

- Carbon steel
- Stainless steel

Environments

The CSS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air - outdoor
- Air with borated water leakage
- Closed-cycle cooling water
- Concrete
- Gas
- Lubricating oil
- Raw water
- Treated borated water

Aging Effects Requiring Management

The following aging effects associated with the CSS require management:

- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the CSS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Open-Cycle Cooling Water System (B.2.3.11)
- Water Chemistry (B.2.3.2)

3.2.2.1.4. Residual Heat Removal System

Materials

The materials of construction for the RHRS components are:

- Carbon steel
- Stainless steel

Environments

The RHRS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Treated borated water
- Treated borated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the RHRS require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the RHRS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.2.2.1.5. Safety Injection System

Materials

The materials of construction for the SIS components are:

- Carbon steel
- Carbon steel with internal coating/lining
- Carbon steel with stainless steel cladding
- Copper alloy
- Gray cast iron
- Stainless steel

Environments

The SIS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Gas
- Lubricating oil
- Raw water
- Treated borated water
- Treated borated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the SIS require management:

- Cracking
- Cumulative fatigue damage
- Loss of coating or lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the SIS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Open-Cycle Cooling Water System (B.2.3.11)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.2.2.2. AMR Results for Which Further Evaluation is Recommended by the GALL Report

The AMR summaries for the CPNPP ESF provides the basis for Section 3.2.2.2 and are compiled from Section 3.2.2.1. NUREG-1801 provides the basis for identifying those programs that warrant FE by the reviewer in the LRA. For the ESF, those programs are addressed in the following subsections.

Note - *Italicized* text is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.2.2.2.1. Cumulative Fatigue Damage

Fatigue is a time-limited aging analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

Where identified as an AERM, as summarized in item 3.2-1, 001, the analysis of fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are evaluated in accordance with 10 CFR 54.21(c). Evaluation of this TLAA for RHR, SI, and (non-ASME Class 1) reactor coolant piping is addressed in Section 4.3.3.

3.2.2.2.2. Loss of Material due to Cladding Breach

Loss of material due to cladding breach could occur for PWR steel pump casings with stainless steel cladding exposed to treated borated water. The GALL Report references NRC Information Notice 94-63, Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks, and recommends further evaluation of a plant-specific AMP to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

There are no steel pump casings with stainless steel cladding in the ESF Systems at CPNPP. Pump casings are stainless steel as summarized in item 3.2-1, 002.

3.2.2.2.3. Loss of Material due to Pitting and Crevice Corrosion

1. *Loss of material due to pitting and crevice corrosion could occur in partially encased stainless steel tanks exposed to raw water due to cracking of the perimeter seal from weathering. The GALL Report recommends further evaluation to ensure that the aging effect is adequately managed. The GALL Report recommends that a plant-specific AMP be evaluated because moisture and water can egress under the tank if the perimeter seal is degraded. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).*

As summarized in item 3.2-1, 003, there are no partially encased tanks exposed to weathering in the ESF Systems at CPNPP. Other than the RWST, tanks and valve isolation tanks (associated with containment sump recirculation components) are located indoors and sheltered from the weather. As listed in Section 2.3.2.3 and described in Section 2.4.11, the RWST for each unit is a missile-protected, Seismic Category I concrete structure with an internal lining that is fully encased and sheltered from the weather.

2. *Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.*

   GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external pitting or crevice corrosion is not expected. The GALL Report recommends further evaluation to determine whether an aging management program is needed to manage this aging effect based on the environmental conditions applicable to the plant and requirements applicable to the components.

Located in Somervell County in North Central Texas, CPNPP is about 65 miles southwest of the Dallas-Fort Worth Metropolitan Area. In addition, the Squaw Creek Reservoir (SCR), built for station cooling, extends northward into Hood County. The site is situated along Squaw Creek, a tributary of the Paluxy River, which is a tributary of the Brazos River. The station site is over 30 miles southwest of the nearest portion of Fort Worth and approximately 4.5 miles north-northwest of Glen

Rose, the nearest community. Hood and Somervell counties are essentially rural, sparsely populated areas. The sparsely settled rural character extends well beyond the 10-mile radius. The area extending from 10 to 20 miles out from the CPNPP site is even more sparsely populated than the 0 to 10-mile area. As such, CPNPP is located inland in a rural area and away from potentially chloride heavy coastal environments or sulfate heavy industrial environments. As confirmed by OE, samples of groundwater and rainwater show chloride and sulfate concentrations less than 500 parts per million (ppm) and 1,500 PPM, respectively, with adequate pH. Furthermore, the CPNPP does not incorporate cooling towers. Also, the closest highway is U.S. Highway 67 that passes through Glen Rose (as shown on google/maps) and the use of salt/ash to de-ice roadways is a rare occurrence in the moderate north-central Texas environs.

As such, the general ambient outdoor and indoor air is considered to be benign, non-aggressive lacking sufficient halides for corrosion of stainless steel.

Therefore, stainless steel components exposed to air environments (including condensation) in the ESF Systems are not susceptible to loss of material and do not require management.

As summarized in item 3.2-1, 004, there are select instances where corrosion of stainless steel in air is considered possible and managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. A plant-specific note is used for these instances.

3.2.2.2.4. Loss of Material due to Erosion

Loss of material due to erosion could occur in the stainless steel high-pressure safety injection (HPSI) pump miniflow recirculation orifice exposed to treated borated water. The GALL Report recommends a plant-specific AMP be evaluated for erosion of the orifice due to extended use of the centrifugal HPSI pump for normal charging. The GALL Report references Licensee Event Report (LER) 50- 275/94-023 for evidence of erosion. Further evaluation is recommended to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).

As summarized in item 3.2-1, 005, CPNPP will implement a One-Time Inspection (B.2.3.19) AMP to verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage the loss of material due to erosion in stainless steel SI and CCP minimum flow recirculation orifices exposed to treated borated water in the SIS and CVCS. CPNPP will perform a one-time inspection of one orifice on each unit associated with the CCP minimum flow recirculation orifice (which are considered bounding because of the frequency of operation of the CCPs compared with the SI pumps) prior to entering the PEO.

3.2.2.2.5. Loss of Material due to General Corrosion and Fouling that Leads to Corrosion

Loss of material due to general corrosion and fouling that leads to corrosion can occur for steel drywell and suppression chamber spray system nozzle and flow orifice internal surfaces exposed to air -indoor uncontrolled. This could result in *plugging of the spray nozzles and flow orifices. This aging mechanism and effect will apply since the spray nozzles and flow orifices are occasionally wetted, even though the majority of the time this system is on standby. The wetting and drying of these components can accelerate corrosion and fouling. The GALL Report recommends further evaluation of a plant-specific AMP to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RSLB-1 (Appendix A.1 of this SRP-LR).*

This paragraph in NUREG-1800 applies to BWRs only.

3.2.2.2.6. Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an aging management program is needed to manage this aging effect based on the environmental conditions applicable to the plant and requirements applicable to the components.

The outdoor environment at CPNPP is described in Section 3.2.2.2.3, item 2 above. As described there, the outdoor air does not contain sufficient halides for degradation of stainless steel components in air. A review of CPNPP OE and evaluation of the location and surroundings of the plant have determined that the air at CPNPP does not contain sufficient halides nor are there events that would likely increase the halide content in the air to make SCC an AERM. As such, and as summarized in item 3.2-1, 006, stainless steel components exposed to air environments (including condensation) in the ESF Systems are not susceptible to cracking and do not require management for SCC. The RWSTs are outdoor reinforced concrete tanks with stainless steel liners as described in Section 2.4.11.

3.2.2.2.7. Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2 of this SRP-LR.)

QA provisions applicable to LR are discussed in Section B.1.3.

3.2.2.2.8. Ongoing Review of Operating Experience (per LR-ISG-2011-05)

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

The OE process and acceptance criteria are described in Section B.1.4.

3.2.2.2.9. Loss of Material due to Recurring Internal Corrosion (per LR-ISG-2012-02)

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness).

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.

The CPNPP corrective action program (CAP) tracks and trends recurring issues, extent of condition (EOC), and includes recommendations to prevent recurrence, where appropriate. None of the ESF Systems have demonstrated corrosion that meets the criteria to be considered recurring internal corrosion (RIC). Therefore, as summarized in item 3.2-1, 066, RIC is not an applicable aging effect for metals in CPNPP ESF Systems containing raw water. The only ESF components containing raw water are the tube-side components of the SI pump bearing and lubrication oil coolers. As such, credited AMPs, such as Fire Water, Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components, and Open Cycle Cooling Water, do not require enhancements to address RIC in ESF Systems.

3.2.2.3. Time-Limited Aging Analysis

The TLAAs identified below are associated with the ESF:

- Section 4.3, “Metal Fatigue”
- Section 4.4, “Environmental Qualification of Electrical Equipment”

3.2.3. Conclusion

The ESF System piping, fittings, and components that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the ESF System components are identified in the summaries in Section 3.2.2.1 above.

A description of these AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the PEO.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the ESF components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the PEO.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 001	Stainless steel, Steel Piping, piping components, and piping elements exposed to Treated water (borated)	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 “Metal Fatigue,” for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See SRP subsection 3.2.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect assessed by a fatigue TLAA (Section 4.3). Further evaluation is documented in subsection 3.2.2.2.1.
3.2-1, 002	Steel (with stainless steel cladding) Pump casings exposed to Treated water (borated)	Loss of material due to cladding breach	A plant-specific aging management program is to be evaluated Reference NRC IN 94-63, “Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks."	Yes, verify that plant-specific program addresses clad breach (See SRP subsection 3.2.2.2.2)	Not applicable. There are no pump casings with stainless steel cladding in the ESF Systems. As listed in Tables 3.2.2-3, 3.2.2-4, and 3.2.2-5 ESF pumps exposed to treated borated water are stainless steel.
3.2-1, 003	Stainless steel Partially-encased tanks with breached moisture barrier exposed to Raw water	Loss of material due to pitting and crevice corrosion	A plant-specific aging management program is to be evaluated for pitting and crevice corrosion of tank bottom because moisture and water can egress under the tank due to cracking of the perimeter seal from weathering.	Yes, plant-specific (See SRP subsection 3.2.2.2.3.1)	Not applicable. There are no partially encased tanks with breached moisture barriers in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 004	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See SRP subsection 3.2.2.2.3.2)	Consistent with NUREG-1801. Loss of material for stainless steel vents and top of the liner inside the concrete RWST is exposed to outdoor air through tank vents and contaminants may collect. Loss of material for the containment spray components is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. A plant-specific note is used. In general, air at CPNPP does not contain sufficient halides to make loss of material due to pitting and crevice corrosion a concern. Further evaluation is documented in subsection 3.2.2.2.3, item 2.
3.2-1, 005	Stainless steel Orifice (miniflow recirculation) exposed to Treated water (borated)	Loss of material due to erosion	A plant-specific aging management program is to be evaluated for erosion of the orifice due to extended use of the centrifugal HPSI pump for normal charging. See LER 50-275/94-023 for evidence of erosion.	Yes, plant-specific (See SRP subsection 3.2.2.2.4)	Consistent with NUREG-1801. Loss of material of the stainless steel orifice (mini-flow recirculation) exposed to treated borated water in the SIS is managed by the One-Time Inspection (B.2.3.19) AMP. Further evaluation is documented in subsection 3.2.2.2.4.
3.2-1, 006	Not applicable. This line item only applies to BWRs.				

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 007	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See SRP subsection 3.2.2.2.6)	Not applicable. Air does not contain sufficient halides to make SCC a concern. Further evaluation is documented in subsection 3.2.2.2.6.
3.2-1, 008	Aluminum, Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements exposed to Air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, "Boric Acid Corrosion"	No	Not applicable. There are no aluminum or copper alloy (>15% Zn or >8% Al) ESF components exposed to air with borated water leakage.
3.2-1, 009	Steel External surfaces, Bolting exposed to Air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, "Boric Acid Corrosion"	No	Consistent with NUREG-1801. Loss of material of steel external surfaces and bolting exposed to air with borated water leakage in the ESF Systems is managed by the Boric Acid Corrosion (B.2.3.4) AMP.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 010	Cast austenitic stainless steel Piping, piping components, and piping elements exposed to Treated water (borated) >250°C (>482°F), Treated water >250°C (>482°F)	Loss of fracture toughness due to thermal aging embrittlement	Chapter XI.M12, "Thermal Aging Embrittlement of Cast Austenitic Stainless Steel"	No	Not applicable. There are no CASS components exposed to treated water (borated) >250°C (>482°F) or treated water >250°C (>482°F) in the ESF Systems.
3.2-1, 011	Not applicable. This line item only applies to BWRs.				
3.2-1, 012	Steel, high-strength Closure bolting exposed to Air with steam or water leakage	Cracking due to cyclic loading, stress corrosion cracking	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no high-strength steel closure bolting in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 013	Steel; stainless steel Bolting, Closure bolting exposed to Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of material of steel and stainless steel bolting and closure bolting exposed to air – indoor, uncontrolled (external) in the ESF Systems is managed by the Bolting Integrity (B.2.3.9) AMP. Loss of material of stainless steel bolting and closure bolting exposed to air – indoor, uncontrolled (external) in the RCS and attached piping is managed by the Bolting Integrity (B.2.3.9) AMP. There are no steel or stainless steel bolting or closure bolting exposed to air – outdoor (external) in the ESF Systems.
3.2-1, 014	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity"	No	Not used. As stated in item 3.2-1, 013, loss of material of steel bolting exposed to air in the ESF Systems is managed by the Bolting Integrity (B.2.3.9) AMP. However, steam or water leakage is not considered as a separate aspect of the indoor air environment.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 015	Copper alloy, Nickel alloy, Steel; stainless steel, Stainless steel, Steel; stainless steel Bolting, Closure bolting exposed to Any environment, Air – outdoor (External), Raw water, Treated borated water, Fuel oil, Treated water, Air – indoor, uncontrolled (External)	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of preload of steel and stainless steel bolting in the ESF Systems is managed by the Bolting Integrity (B.2.3.9) AMP. There are no copper alloy or nickel alloy bolting in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 016	Steel Containment isolation piping and components (Internal surfaces), Piping, piping components, and piping elements exposed to Treated water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not used. Loss of material of steel containment isolation components (piping and valve bodies) exposed to treated water is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. However, steel containment isolation components exposed to treated water are evaluated as part of their respective auxiliary or steam and power conversion systems and compared to items 3.4-1, 013 and 3.4-1, 014.
3.2-1, 017	Not applicable. This line item only applies to BWRs.				

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 018	Stainless steel Containment isolation piping and components (Internal surfaces) exposed to Treated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801. Loss of material of stainless steel containment isolation components (piping and valve bodies) exposed to treated water in the non-ASME Class 1 portion of the RCS, as well as for other components inside containment, is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Other stainless steel containment isolation components (piping and valve bodies) exposed to treated water are evaluated as part of their respective auxiliary or steam and power conversion systems and compared to item 3.4-1, 016.
3.2-1, 019	Stainless steel Heat exchanger tubes exposed to Treated water, Treated water (borated)	Reduction of heat transfer due to fouling	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2011-01. Reduction of heat transfer of stainless steel heat exchanger tubes exposed to treated water and treated borated water in the ESF Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage reduction of heat transfer.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 020	Stainless steel Piping, piping components, and piping elements; tanks exposed to Treated water (borated) >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry" and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2011-01. Cracking of stainless steel components exposed to treated borated water >140°F in the ESF Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking.
3.2-1, 021	Steel (with stainless steel or nickel-alloy cladding) Safety injection tank (accumulator) exposed to Treated water (borated) >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry" and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. The CPNPP SI accumulators are maintained at containment ambient conditions (<140°F).

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 022	Stainless steel Piping, piping components, and piping elements; tanks exposed to Treated water (borated)	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2011-01. Loss of material of stainless steel components exposed to treated borated water in the ESF Systems, as well as RCS components that are not ASME Class 1, is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material.
3.2-1, 023	Steel Heat exchanger components, Containment isolation piping and components (Internal surfaces) exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no steel heat exchangers in the ESF Systems exposed to raw water.
3.2-1, 024	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no stainless steel piping, piping components, and piping elements exposed to raw water in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 025	Stainless steel Heat exchanger components, Containment isolation piping and components (Internal surfaces) exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. Loss of material of stainless steel heat exchanger components exposed to raw water in the ESF Systems is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP.
3.2-1, 026	Not applicable. This line item only applies to BWRs.				
3.2-1, 027	Stainless steel, Steel Heat exchanger tubes exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. Reduction of heat transfer of stainless steel heat exchanger (pump bearing oil cooler) tubes exposed to raw water in the CSS is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP.
3.2-1, 028	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no stainless steel piping, piping components, and piping elements exposed to closed-cycle cooling water >60°C (>140°F) in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 029	Steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no steel piping, piping components, and piping elements exposed to closed-cycle cooling water in the ESF Systems.
3.2-1, 030	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of steel heat exchanger components exposed to closed-cycle cooling water in the ESF Systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801.
3.2-1, 031	Stainless steel Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of stainless steel heat exchanger components exposed to closed-cycle cooling water in the ESF Systems, as well as RCP thermal barrier heat exchanger components in the RCS, is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. There are no stainless steel piping, piping components, and piping elements exposed to closed-cycle cooling water in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 032	Copper alloy Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no copper alloy heat exchanger components, piping, piping components, and piping elements exposed to closed-cycle cooling water in the ESF Systems.
3.2-1, 033	Copper alloy, Stainless steel Heat exchanger tubes exposed to Closed-cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Reduction of heat transfer of stainless steel heat exchanger tubes exposed to closed-cycle cooling water in the ESF Systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. There are no copper alloy heat exchanger tubes exposed to closed cycle cooling water in the ESF Systems.
3.2-1, 034	Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements, Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Not applicable. There are no copper alloy (>15% Zn or >8% Al) piping, piping components, and piping elements, heat exchanger components exposed to closed-cycle cooling water in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 035	Gray cast iron Motor cooler exposed to Treated water	Loss of material due to selective leaching	Chapter XI.M33, "Selective Leaching"	No	Not applicable. There are no gray cast iron motor coolers exposed to treated water in the ESF Systems.
3.2-1, 036	Gray cast iron Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to selective leaching	Chapter XI.M33, "Selective Leaching"	No	Not applicable. There are no gray cast iron piping, piping components, and piping elements exposed to closed-cycle cooling water in the ESF Systems.
3.2-1, 037	Gray cast iron Piping, piping components, and piping elements exposed to Soil	Loss of material due to selective leaching	Chapter XI.M33, "Selective Leaching"	No	Not applicable. There are no gray cast iron piping, piping components, and piping elements exposed to soil in the ESF Systems.
3.2-1, 038	Not applicable. This line item only applies to BWRs.				

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 039	Steel Containment isolation piping and components (External surfaces) exposed to Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not used. As stated in item 3.2-1, 040, loss of material of containment isolation piping and piping components (External surfaces) exposed to air in the ESF Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Furthermore, steel containment isolation piping and components exposed to condensation are evaluated as part of the Auxiliary System to which they are assigned and compared to a different NUREG-1801 item, such as 3.3-1, 132.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 040	Steel Ducting, piping, and components (External surfaces), Ducting, closure bolting, Containment isolation piping and components (External surfaces) exposed to Air – indoor, uncontrolled (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. Loss of material of steel ducting, piping, and components (external surfaces), ducting, containment isolation piping and piping components (external surfaces) exposed to air – indoor, uncontrolled (external) in the ESF Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Loss of material of steel piping and piping components (external surfaces) exposed to air – indoor, uncontrolled (external) in the non-ASME Class 1 portion of the RCS is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Loss of material for steel closure bolting exposed to air – indoor, uncontrolled (external) in the ESF Systems is addressed by item 3.2-1, 013.
3.2-1, 041	Steel External surfaces exposed to Air – outdoor (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no steel surfaces exposed to air – outdoor (external) in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 042	Aluminum Piping, piping components, and piping elements exposed to Air -outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no aluminum piping, piping components, and piping elements exposed to air – outdoor (external) in the ESF Systems.
3.2-1, 043	Not applicable. This line item only applies to BWRs.				
3.2-1, 044	Steel Piping and components (Internal surfaces), Ducting and components (Internal surfaces) exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to general corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material of steel piping and piping components (internal surfaces) exposed to air – indoor, uncontrolled (internal) in the ESF Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Loss of material of steel piping and piping components (internal surfaces) and ducting and components (internal surfaces) exposed to air – indoor, uncontrolled (internal) in the Containment Ventilation, Control Room Ventilation Systems, Miscellaneous Ventilation Systems, Primary Plant Ventilation Systems, SSW, CCW System, Compressed Air and Gas Systems, EDG and Auxiliary Systems, Ventilation Chilled Water Systems, and AFWS is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 045	Steel Encapsulation components exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not used. The encapsulation (valve isolation) components exposed to air – indoor, uncontrolled (internal) in the ESF Systems are stainless steel and addressed in item 3.2-1, 063. A plant-specific note is used. Loss of material for the steel recirculation sump effluent guard pipe exposed to air – indoor uncontrolled (internal), which with the valve isolation components encapsulates ESF recirculation piping and valves, is addressed in item 3.5-1, 077. A plant-specific note is used.
3.2-1, 046	Not applicable. This line item only applies to BWRs.				
3.2-1, 047	Steel Encapsulation components exposed to Air with borated water leakage (Internal)	Loss of material due to general, pitting, crevice, and boric acid corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no steel encapsulation components exposed to air – indoor, uncontrolled (internal) in the ESF Systems. Steel recirculation sump effluent guard are not exposed internally to borated water leakage during normal operation.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 048	Stainless steel Piping, piping components, and piping elements (Internal surfaces); tanks exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no stainless steel piping, piping components, and piping elements (internal surfaces); tanks exposed to condensation (internal) in the ESF Systems.
3.2-1, 049	Steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. Loss of material of steel piping, piping components, as well as tank and heat exchanger shell, exposed to lubricating oil in the ESF Systems is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 050	Copper alloy, Stainless steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of copper alloy, and stainless steel piping, piping components, and piping elements exposed to lubricating oil in the ESF Systems, as well as piping and heat exchangers in non-ASME Class 1 portion of the RCS, is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 051	Steel, Copper alloy, Stainless steel Heat exchanger tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. Reduction of heat transfer of copper alloy and stainless steel heat exchanger tubes exposed to lubricating oil in the ESF Systems is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage reduction of heat transfer. Reduction of heat transfer of copper alloy heat exchanger tubes exposed to lubricating oil in the CVCS and EDG and Auxiliary Systems, as well as stainless steel heat exchanger tubes in the SSW System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage reduction of heat transfer.
3.2-1, 052	Steel (with coating or wrapping) Piping, piping components, and piping elements exposed to Soil or Concrete	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no steel (with coating or wrapping) piping, piping components, and piping elements exposed to soil or concrete in the ESF Systems, as clarified below. The steel recirculation sump effluent guard pipe, which encapsulates ESF recirculation components, is embedded in the concrete of the containment and addressed in item 3.3-1, 112. A plant-specific note is used.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 053	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not used. There are no stainless steel, nickel alloy piping, piping components, and piping elements exposed to soil in the ESF Systems. Stainless steel tubing exposed to concrete in the CSS is addressed by item 3.2-1, 063.
3.2-1, 053.5	Steel, stainless steel, nickel alloy underground piping, piping components, and piping elements exposed to air-indoor uncontrolled or condensation (external)	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not used. There are no steel or nickel alloy underground piping, piping components, and piping elements exposed to air-indoor uncontrolled or condensation (external) in the ESF Systems. As noted in Table 2.2-3, the connected tunnel to the concrete RWST, for each unit, are accessible and considered another room/area of the Safeguards Building. As such, stainless steel piping and valves in the CSS, that are below-grade in the tunnel, are included in item 3.2-1, 063 along with other ESF piping and piping components.
3.2-1, 054	Not applicable. This line item only applies to BWRs.				

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 055	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. There are no steel piping and piping components exposed to concrete in the ESF Systems. The steel recirculation sump effluent guard pipe, which encapsulates ESF recirculation components, is embedded in the concrete of the containment and addressed in item 3.3-1, 112.
3.2-1, 056	Aluminum Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External)	None	None	NA -No AEM or AMP	Not applicable. There are no aluminum piping and piping components exposed to air – indoor, uncontrolled (internal/external) in the ESF Systems.
3.2-1, 057	Copper alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Gas	None	None	NA -No AEM or AMP	Not applicable. There are no copper alloy piping and piping components exposed to air – indoor, uncontrolled (external) or gas in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 058	Copper alloy (≤15% Zn and ≤8% Al) Piping, piping components, and piping elements exposed to Air with borated water leakage	None	None	NA -No AEM or AMP	Not applicable. There are no copper alloy (≤15% Zn and ≤8% Al) piping, piping components, and piping elements exposed to air with borated water leakage in the ESF Systems. Copper alloy ESF filtration components are included with plant ventilation systems addressed in item 3.3-1, 115.
3.2-1, 059	Galvanized steel Ducting, piping, and components exposed to Air – indoor, controlled (External)	None	None	NA -No AEM or AMP	Not applicable. There are no galvanized steel ducting, piping, and components exposed to air – indoor, controlled (external) in the ESF Systems. Galvanized steel ESF filtration components are included with Plant Ventilation Systems addressed in item 3.3-1, 116.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 060	Glass Piping elements exposed to Air – indoor, uncontrolled (External), Lubricating oil, Raw water, Treated water, Treated water (borated), Air with borated water leakage, Condensation (Internal/External), Gas, Closed-cycle cooling water, Air – outdoor	None	None	NA -No AEM or AMP	Not applicable. There are no glass piping elements exposed to air – indoor, uncontrolled (external), lubricating oil, raw water, treated water, treated water (borated), air with borated water leakage, condensation (internal/external), gas, closed-cycle cooling water, or air – outdoor in the ESF Systems.
3.2-1, 061	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA -No AEM or AMP	Not applicable. There are no nickel alloy piping, piping components, and piping elements exposed to air – indoor, uncontrolled (external) in the ESF Systems.
3.2-1, 062	Nickel alloy Piping, piping components, and piping elements exposed to Air with borated water leakage	None	None	NA -No AEM or AMP	Not applicable. There are no nickel alloy piping, piping components, and piping elements exposed to air with borated water leakage in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 063	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Air with borated water leakage, Concrete, Gas, Air – indoor, uncontrolled (Internal)	None	None	NA -No AEM or AMP	Consistent with NUREG-1801. Includes stainless steel ESF piping and piping components, pump casings, tanks, heat exchanger components, and valve isolation components (which encapsulate ESF recirculation components) exposed to air – indoor uncontrolled and gas (and air with borated water leakage that is not listed for stainless steel). Includes the RWST liner that is encased in the concrete of the tank. Also includes stainless steel piping and components in the SSW System that are empty (contains Air – indoor, uncontrolled).
3.2-1, 064	Steel Piping, piping components, and piping elements exposed to Air – indoor, controlled (External), Gas	None	None	NA -No AEM or AMP	Consistent with NUREG-1801.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 065	Any material, piping, piping components, and piping elements exposed to treated water, treated water (borated)	Wall thinning due to erosion	Chapter XI.M17, “Flow-Accelerated Corrosion”	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2012-01. Wall thinning of stainless steel piping, piping components, and piping elements exposed to treated borated water in the ESF Systems is managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801.
3.2-1, 066	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See SRP subsection 3.2.2.2.9)	Not applicable. Loss of material due to recurring internal corrosion has not been identified in metallic piping, piping components, and tanks exposed to raw water or waste water in the ESF Systems. Further evaluation is documented in subsection 3.2.2.2.9.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 067	Stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Cracking due to stress corrosion cracking	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete in the ESF Systems. Aboveground outdoor tanks in the ESF Systems include the missile-protected, stainless steel-lined concrete RWST in the CSS. The RWST lining exposed to air -outdoor (above water line through vents in the concrete tank) and concrete is included in items 3.2-1, 004, and 3.2-1, 063, respectively. The concrete RWST components are addressed in items 3.5-1, 043, 3.5-1, 044, 3.5-1, 054, 3.5-1, 063, 3.5-1, 066, and 3.5-1, 067.
3.2-1, 068	Steel, stainless steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, or condensation in the ESF Systems. The stainless steel lined concrete RWST in the CSS is addressed in item 3.2-1, 067 above.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 069	Insulated steel, stainless steel, copper alloy, or aluminum, piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy only), pitting, and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, "Aboveground Metallic Tanks," (for tanks only)	No	Not applicable. There are no insulated steel, stainless steel, copper alloy, or aluminum, piping, piping components, and tanks exposed to condensation, air-outdoor in the ESF Systems, as clarified in item 3.2-1, 039 above.
3.2-1, 070	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to treated water, treated borated water	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to treated water or treated borated water in the ESF Systems. Loss of material for the stainless steel liner of the concrete RWST in the CSS exposed to treated borated water is addressed in item 3.2-1, 022. Other than the stainless steel-lined concrete RWST, tanks in the ESF Systems are located indoors with volumes less than 100,000 gallons and do not meet the scope of XI.M29 as supplemented by LR-ISG-2012-02.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.2-1, 071	Insulated stainless steel, aluminum, or copper alloy (>15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, "Aboveground Metallic Tanks," (for tanks only)	No	Not applicable. There are no insulated stainless steel, aluminum, or copper alloy (>15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor in the ESF Systems.
3.2-1, 072	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage, and spalling for cementitious coatings/linings	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Loss of coating or lining integrity for the SI pump lubricating oil cooler reservoir exposed to lubricating oil is managed by the Lubricating Oil Analysis (B.2.3.25) AMP and One-Time Inspection (B.2.3.19) AMP. A generic note E and a plant-specific note are used. There are no metallic components with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, or treated borated water in the ESF Systems.

Table 3.2-1: Summary of Aging Management Programs for Engineered Safety Features

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.2-1, 073	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Loss of material for the SI pump lubricating oil cooler reservoir exposed to lubricating oil is managed by the Lubricating Oil Analysis (B.2.3.25) AMP and One-Time Inspection (B.2.3.19) AMP. A generic note E and a plant-specific note are used.
3.2-1, 074	Gray cast iron piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. There are no gray cast iron piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water in the ESF Systems.

Table 3.2.2-1: Combustible Gas Control Systems – Summary of Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect Requiring Management	Aging Management Programs	NUREG-1801 Item	Table 1 Item	Notes
Bolting	Mechanical closure	Stainless steel	Air - indoor uncontrolled (external)	Loss of material	Bolting Integrity (B.2.3.9)	V.E.EP-70	3.2-1, 013	A
Bolting	Mechanical closure	Stainless steel	Air - indoor uncontrolled (external)	Loss of preload	Bolting Integrity (B.2.3.9)	V.E.EP-69	3.2-1, 015	A
Bolting	Mechanical closure	Carbon steel	Air - indoor uncontrolled (external)	Loss of material	Bolting Integrity (B.2.3.9)	V.E.EP-70	3.2-1, 013	A
Bolting	Mechanical closure	Carbon steel	Air - indoor uncontrolled (external)	Loss of preload	Bolting Integrity (B.2.3.9)	V.E.EP-69	3.2-1, 015	A
Bolting	Mechanical closure	Carbon steel	Air with borated water leakage (external)	Loss of material	Boric Acid Corrosion (B.2.3.4)	V.E.E-41	3.2-1, 009	A
Damper housing	Pressure boundary	Carbon steel	Air - indoor uncontrolled (external)	Loss of material	External Surfaces Monitoring of Mechanical Components (B.2.3.22)	V.A.E-26	3.2-1, 040	A
Damper housing	Pressure boundary	Carbon steel	Air - indoor uncontrolled (internal)	Loss of material	Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)	V.A.E-29	3.2-1, 044	C
Damper housing	Pressure boundary	Carbon steel	Air with borated water leakage (external)	Loss of material	Boric Acid Corrosion (B.2.3.4)	V.D1.E-28	3.2-1, 009	A
Orifice	Pressure boundary	Stainless steel	Air - indoor uncontrolled (external)	None	None	V.F.EP-18	3.2-1, 063	A
Orifice	Pressure boundary	Stainless steel	Air - indoor uncontrolled (internal)	None	None	V.F.EP-82	3.2-1, 063	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

None.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

1. Components are associated with the containment personnel airlock hydraulics. Hydraulic fluid is included with the lubricating oil environment as stated in Table 3.0-1.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

Plant-Specific Notes

1. The internal stainless steel liner associated with the missile protected RWST is evaluated in this AMR. The concrete portion of the RWST, including the roof, is evaluated with the Yard structures in Table 3.5.2-11. Furthermore, the configuration does not allow water to get between the liner and the concrete.

2. Vent piping atop the concrete roof of the RWST are open to the outdoor air as, conservatively, are the liner and makeup/vent lines inside the RWST above the waterline.

3. Valve isolation tank and associated components are designed to contain leakage during recirculation from the containment recirculation sumps. In addition, the tank and associated components are attached to the guard pipe and containment penetrations MS-3 and MS-4, which are addressed in Table 3.5.2-1 and contain nuclear safety related recirculation piping and valves. As such, the valve isolation tank, and associated components (e.g., draining and level) are assigned both a leakage boundary (spatial) and structural integrity (attached) function.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

Plant-Specific Notes

1. Valve isolation tank and associated components are designed to contain leakage during recirculation from the Containment recirculation sumps. In addition, the tank and associated components are attached to the guard pipe and Containment penetrations MS-1 and MS-2, which are addressed in Table 3.5.2-1 and contain safety related recirculation piping and valve. As such, the valve isolation tank, and associated components (e.g., draining and level) are assigned both a leakage boundary (spatial) and structural integrity (attached) function.

2. Piping and tubing associated with the following components have an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4: RHR hot leg loops 1 and 4, RCP seal water injection line.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

1. Components listed with environments of internal borated water above 140°F are only applicable for those components attached or connected to the RCS that are cycled during plant startup/cooldown.

2. Piping associated with the following components has an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4: ECCS/boron Injection tank (BIT) cold legs 1, 2, 3, and 4; accumulator cold legs 1, 2, 3, and 4; SI/RHR return; SIS connection to accumulator.

3. Exception taken in the Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) AMP to manage aging effects of the internally coated SI pump lube oil cooler reservoirs under the Lubricating Oil Analysis (B.2.3.25) and One-Time Inspection (B.2.3.19) AMPs.

3.3. AGING MANAGEMENT OF AUXILIARY SYSTEMS

3.3.1. Introduction

This section provides the results of the AMR for those components identified in Section 2.3.3, "Auxiliary Systems", as being subject to AMR. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Chemical and Volume Control System (2.3.3.1)
- Component Cooling Water System (2.3.3.2)
- Compressed Air and Gas Systems (2.3.3.3)
- Demineralized and Reactor Makeup Water System (2.3.3.4)
- Emergency Diesel Generator and Auxiliary Systems (2.3.3.5)
- Equipment and Floor Drainage System (2.3.3.6)
- Fire Protection System (2.3.3.7)
- Plant Ventilation Systems (2.3.3.8)
- Potable and Sanitary Water System (2.3.3.9)
- Process and Effluent Radiological Monitoring and Sampling System (2.3.3.10)
- Spent Fuel Pool Cooling and Cleanup System (2.3.3.11)
- Station Service Water System (2.3.3.12)
- Ventilation Chilled Water Systems (2.3.3.13)
- Waste Processing Systems (2.3.3.14)

3.3.2. Results

The following tables summarize the results of the AMR for Auxiliary Systems.

Table 3.3.2-1: Chemical and Volume Control System – Summary of Aging Management Evaluation

Table 3.3.2-2: Component Cooling Water System – Summary of Aging Management Evaluation

Table 3.3.2-3: Compressed Air and Gas Systems – Summary of Aging Management Evaluation

3.3.2.1. Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.3.2.1.1. Chemical and Volume Control System

Materials

The materials of construction for the CVCS components are:

- Carbon steel
- Copper alloy
- Copper alloy > 15% Zn or > 8% Al
- Glass
- Stainless steel

Environments

The CVCS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Closed-cycle cooling water > 140°F
- Condensation
- Gas
- Lubricating oil
- Raw water
- Treated borated water
- Treated borated water > 140°F
- Treated water
- Treated water > 140°F
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the CVCS require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the CVCS components:

- ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1)
- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Open-Cycle Cooling Water (B.2.3.11)
- Selective Leaching (B.2.3.20)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.3.2.1.2. <u>Component Cooling Water System</u>

Materials

The materials of construction for the CCW System components are:

- Carbon steel
- Carbon steel with internal coating
- Cast iron
- Copper alloy
- Glass
- Nickel alloy
- Stainless alloy

Environments

The CCW System components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Condensation
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the CCW System require management:

- Loss of coating/lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the CCW System components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28)
- Open-Cycle Cooling Water (B.2.3.11)
- Selective Leaching (B.2.3.20)

3.3.2.1.3. Compressed Air and Gas Systems

Materials

The materials of construction for the Compressed Air and Gas Systems components are:

- Carbon steel
- Copper alloy
- Copper alloy > 15% Zn or > 8% Al
- Elastomer
- Stainless steel

Environments

The Compressed Air and Gas Systems components are exposed to the following environments:

- Air – dry
- Air – indoor uncontrolled
- Air with borated water leakage
- Gas

Aging Effects Requiring Management

The following aging effects associated with the Compressed Air and Gas Systems require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the Compressed Air and Gas Systems components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Compressed Air Monitoring (B.2.3.14)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

3.3.2.1.4. Demineralized and Reactor Makeup Water System

Materials

The materials of construction for the DRMWS components are:

- Carbon steel
- Elastomer
- Stainless steel

Environments

The DRMWS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Concrete
- Gas
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the DRMWS require management:

- Hardening and loss of strength
- Loss of material
- Loss of preload
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the DRMWS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- One-Time Inspection (B.2.3.19)
- Water Chemistry (B.2.3.2)

3.3.2.1.5. Emergency Diesel Generator and Auxiliary Systems

Materials

The materials of construction for the EDG and Auxiliary Systems components are:

- Aluminum
- Carbon steel
- Carbon steel with internal coating/lining
- Cast iron
- Copper alloy
- Elastomer
- Glass
- Stainless steel

Environments

The EDG and Auxiliary Systems components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Closed-cycle cooling water
- Closed-cycle cooling water >140°F
- Condensation
- Diesel exhaust
- Fuel oil
- Lubricating oil
- Raw water
- Soil
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the EDG and Auxiliary Systems require management:

- Cracking
- Hardening and loss of strength
- Loss of coating/lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the EDG and Auxiliary components:

- Bolting Integrity (B.2.3.9)
- Buried and Underground Piping and Tanks (B.2.3.27)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Fuel Oil Chemistry (B.2.3.17)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Internal Coatings/Lining for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Open-Cycle Cooling Water System (B.2.3.11)
- Selective Leaching (B.2.3.20)
- Water Chemistry (B.2.3.2)

3.3.2.1.6. Equipment and Floor Drainage Systems

Materials

The materials of construction for the Equipment and Floor Drainage System components are:

- Carbon steel
- Cast iron
- Stainless steel

Environments

The Equipment and Floor Drainage System components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Equipment and Floor Drainage System require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the Equipment and Floor Drainage System components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Selective Leaching (B.2.3.20)

3.3.2.1.7. Fire Protection System

Materials

The materials of construction for the FPS components are:

- Carbon steel
- Carbon steel with internal coating/lining
- Cast iron
- Cement-lined ductile iron
- Copper alloy
- Copper alloy > 15% Zn or > 8% Al
- Elastomer
- Glass
- Stainless steel

Environments

The FPS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Concrete
- Condensation
- Diesel exhaust
- Fuel oil
- Gas
- Raw water
- Soil
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the FPS require management:

- Cracking
- Flow blockage
- Hardening and loss of strength
- Loss of coating/lining integrity
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the FPS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Buried and Underground Piping and Tanks (B.2.3.27)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Fire Protection (B.2.3.15)
- Fire Water System (B.2.3.16)
- Fuel Oil Chemistry (B.2.3.17)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Internal Coatings/Linings of In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28)
- One-Time Inspection (B.2.3.19)
- Selective Leaching (B.2.3.20)

3.3.2.1.8. Plant Ventilation Systems

Containment Ventilation Systems

Materials

The materials of construction for the components of the Containment Ventilation Systems are:

- Carbon steel
- Copper alloy
- Galvanized steel
- Stainless steel

Environments

The components of the Containment Ventilation Systems are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage

- Closed-cycle cooling water
- Condensation
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Containment Ventilation Systems require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the Containment Ventilation Systems components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- One-Time Inspection (B.2.3.19)
- Water Chemistry (B.2.3.2)

<u>Control Room Area Ventilation System</u>

Materials

The materials of construction for the components of the Control Room Area Ventilation System are:

- Carbon steel
- Carbon steel with internal coating/lining
- Copper alloy
- Copper alloy > 15% Zn or >8% Al
- Elastomer
- Fiberglass
- Galvanized steel
- Stainless steel

Environments

The components of the Control Room Area Ventilation System are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor

- Closed-cycle cooling water
- Condensation
- Lubricating oil
- R-12 gas
- Raw water
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Control Room Area Ventilation System require management:

- Blistering
- Cracking
- Hardening and loss of strength
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the Control Room Area Ventilation System components:

- Bolting Integrity (B.2.3.9)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Water Chemistry (B.2.3.2)

<u>Miscellaneous Ventilation Systems</u>

Materials

The materials of construction for the components of the Miscellaneous Ventilation Systems are:

- Aluminum
- Carbon steel
- Carbon steel with internal coating/lining
- Copper alloy
- Copper alloy > 15% Zn
- Elastomer
- Fiberglass
- Galvanized steel
- Stainless steel

Environments

The components of the Miscellaneous Ventilation Systems are exposed to the following environments:

- Air – dry
- Air – indoor uncontrolled
- Air – outdoor
- Closed-cycle cooling water
- Condensation
- R-12 gas
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Miscellaneous Ventilation Systems require management:

- Blistering
- Cracking
- Hardening and loss of strength
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the Miscellaneous Ventilation Systems components:

- Bolting Integrity (B.2.3.9)
- Closed Treated Water Systems (B.2.3.12)
- Compressed Air Monitoring (B.2.3.14)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Selective Leaching (B.2.3.20)

Primary Plant Ventilation Systems

Materials

The materials of construction for the components of the Primary Plant Ventilation Systems are:

- Carbon steel
- Carbon steel with internal coating/lining
- Copper alloy
- Copper alloy > 15% Zn or >8% Al
- Elastomer

- Fiberglass
- Galvanized steel
- Stainless steel

Environments

The components of the Primary Plant Ventilation Systems are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Closed-cycle cooling water
- Condensation
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the Primary Plant Ventilation Systems require management:

- Blistering
- Cracking
- Hardening and loss of strength
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the Primary Plant Ventilation Systems components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- One-Time Inspection (B.2.3.19)
- Selective Leaching (B.2.3.20)
- Water Chemistry (B.2.3.2)

3.3.2.1.9. Potable and Sanitary Water System

Chlorination System

Materials

The materials of construction for the CLS components are:

- PVC

Environments

The CLS components are exposed to the following environments:

- Air – indoor uncontrolled

Aging Effects Requiring Management

The following aging effects associated with the CLS require management:

- None

Aging Management Programs

The following AMPs manage the aging effects for the CLS components:

- None

Potable and Sanitary Water System

Materials

The materials of construction for the PWS components are:

- Copper alloy
- Copper alloy > 15% Zn or > 8% Al
- Stainless steel

Environments

The PWS components are exposed to the following environments:

- Air – indoor uncontrolled
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the PWS require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the PWS components:

- Bolting Integrity (B.2.3.9)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Selective Leaching (B.2.3.20)

3.3.2.1.10. Process and Effluent Radiological Monitoring and Sampling System

Materials

The materials of construction for the Process and Effluent Radiological Monitoring and Sampling System components are:

- Carbon steel
- Stainless steel

Environments

The Process and Effluent Radiological Monitoring and Sampling System components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Concrete
- Gas
- Treated borated water
- Treated borated water > 140°F
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Process and Effluent Radiological Monitoring and Sampling System require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the Process and Effluent Radiological Monitoring and Sampling System components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.3.2.1.11. Spent Fuel Pool Cooling and Cleanup System

Materials

The materials of construction for the SFS components are:

- Carbon steel
- Stainless steel

Environments

The SFS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Concrete
- Treated borated water
- Treated borated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the SFS require management:

- Cracking
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the SFS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)

- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- One-Time Inspection (B.2.3.19)
- Water Chemistry (B.2.3.2)

3.3.2.1.12. Station Service Water System

Materials

The materials of construction for the SSW components are:

- Carbon steel
- Carbon steel with internal coating/lining
- Copper alloy > 15% Zn or > 8% Al
- Nickel alloy
- PVC
- Stainless steel

Environments

The SSW components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Condensation
- Lubricating Oil
- Raw water
- Soil

Aging Effects Requiring Management

The following aging effects associated with the SSW require management:

- Cracking
- Loss of coating or lining integrity
- Loss of material
- Loss of preload
- Reduction of heat transfer
- Wall-thinning

Aging Management Programs

The following AMPs manage the aging effects for the SSW components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Buried and Underground Piping and Tanks (B.2.3.27)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

- Internal Coatings/Lining for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Open-Cycle Cooling Water System (B.2.3.11)
- Selective Leaching (B.2.3.20)

3.3.2.1.13. Ventilation Chilled Water Systems

Materials

The materials of construction for the Ventilation Chilled Water Systems components are:

- Carbon steel
- Cast iron
- Copper alloy
- Copper alloy > 15% Zn or >8% Al
- Glass
- Graphite
- Stainless steel

Environments

The Ventilation Chilled Water Systems components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Condensation
- Lubricating oil
- R-11 gas
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the Ventilation Chilled Water Systems require management:

- Cracking
- Loss of material
- Loss of preload
- Reduction of heat transfer

Aging Management Programs

The following AMPs manage the aging effects for the Ventilation Chilled Water Systems components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Selective Leaching (B.2.3.20)
- Water Chemistry (B.2.3.2)

3.3.2.1.14. Waste Processing Systems

Materials

The materials of construction for the WPS components are:

- Carbon steel
- Stainless steel

Environments

The WPS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water
- Condensation
- Steam
- Waste water
- Waste water >140°F

Aging Effects Requiring Management

The following aging effects associated with the WPS require management:

- Cracking
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the WPS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- TLAA (Section 4.3)

3.3.2.2. AMR Results for Which Further Evaluation is Recommended by the GALL Report

The AMR summaries for the Auxiliary Systems provide the basis for Section 3.3.2.2 and are compiled from Section 3.3.2.1. NUREG-1801 provides the basis for identifying those programs that warrant further evaluation by the reviewer in the LRA. For the Auxiliary Systems, those programs are addressed in the following subsections.

Note - *Italicized* text is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.3.2.2.1. Cumulative Fatigue Damage

Fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," or Section 4.7, "Other Plant-Specific Time-Limited Aging Analyses," of this SRP-LR.

Cumulative fatigue damage affects piping or tubing component types as representative of other component types (e.g., heat exchanger tubes). Where cumulative fatigue damage is identified as an AERM, the analysis of fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are evaluated in accordance with 10 CFR 54.21(c). As summarized in item 3.3-1, 002, evaluation of fatigue for susceptible components in the CVCS and Process Sampling, and Liquid Waste Processing systems is addressed by the TLAA in Section 4.3.3, with the portions attached to the RCS (ASME Class 1) addressed in Section 4.3.2. In addition, as summarized in item 3.3-1, 001, cumulative fatigue damage, with regard to crane load cycle limits, is an aging effect assessed by the TLAA in Section 4.7.4.

3.3.2.2.2. Cracking due Stress Corrosion Cracking and Cyclic Loading

Cracking due to SCC and cyclic loading could occur in stainless steel PWR non-regenerative heat exchanger components exposed to treated borated water greater than 60°C (>140°F) in the chemical and volume control system. The existing aging management program on monitoring and control of primary water chemistry in PWRs manages the aging effects of cracking due to SCC. However, control of water chemistry does not preclude cracking due to SCC and cyclic loading. Therefore, the effectiveness of the water chemistry control *program should be verified to ensure that cracking is not occurring. The GALL Report recommends that a plant-specific aging management program be evaluated to verify the absence of cracking due to SCC and cyclic loading to ensure that these aging effects are managed adequately. An acceptable verification program is to include temperature and radioactivity monitoring of the shell side water, and eddy current testing of tubes.*

As summarized in item 3.3-1, 003, cracking due to SCC and cyclic loading in stainless steel PWR non-regenerative heat exchanger (letdown) components exposed to treated borated water greater than 140°F in the CVCS is an AERM. The Water Chemistry AMP manages cracking of stainless steel non-regenerative heat exchanger components exposed to treated borated water and treated borated water greater than 140°F. The AMP is augmented by the One-Time Inspection (B.2.3.19) AMP which will verify the absence of cracking through the use of appropriate visual, surface, or volumetric NDE techniques. Absence of cracking of the letdown heat exchanger tubes and tubesheet and channel head is also verified by monitoring radiation levels in the CCW system, through the Closed Treated Water Systems (B.2.3.12) AMP. Temperature monitoring is a less sensitive technique and is not used.

3.3.2.2.3. Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements applicable to the components.

Environmental conditions at CPNPP are described in Section 3.2.2.2.3 above. As indicated there and summarized in item 3.3-1, 004, the outdoor air does not contain sufficient halides. A review of CPNPP OE and evaluation of the location and surroundings of the plant have determined that the air at CPNPP does not contain sufficient halides nor are there events that would likely increase the halide content in the air to make cracking (due to stress corrosion cracking) an AERM for stainless steel exposed to air. As such, stainless steel components exposed to air environments in the auxiliary systems, as well as the in the structures and structural commodities are not susceptible to (halide-induced) cracking, which is not expected and does not require management. The RMWSTs are outdoor reinforced concrete tanks with stainless steel liners as described in Section 2.4.11.

3.3.2.2.4. Loss of Material due to Cladding Breach

Loss of material due to cladding breach could occur for PWR steel charging pump casings with stainless steel cladding exposed to treated borated water. The GALL Report references NRC Information Notice 94-63, "Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks," and recommends further evaluation of a plant-specific aging management program to ensure that the aging effect is adequately managed. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

This paragraph in NUREG-1800 pertains to steel charging pump casings with stainless steel cladding. Loss of material could occur for the steel casing material if exposed to treated borated water due to a cladding breach. As summarized in item 3.3-1, 005, the CPNPP charging pump casings are solid stainless steel and loss of material due to cladding breach is not applicable to the centrifugal or positive displacement charging pumps. Furthermore, there are no steel pump casings with stainless steel cladding in the Auxiliary systems.

3.3.2.2.5. Loss of Material due to Pitting and Crevice Corrosion

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those within 1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external pitting or crevice corrosion is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI *requirements Quality Assurance for Aging Management of Nonsafety-Related Components.*

As described in Section 3.2.2.2.3, the outdoor air does not contain sufficient halides for corrosion of stainless steel in air. A review of CPNPP OE and evaluation of the location and surroundings of the plant have determined that the air at CPNPP does not contain sufficient halides nor are there events that would likely increase the halide content in the air to make loss of material (due to pitting and crevice corrosion) an AERM for stainless steel exposed to air except in select instances. As such, stainless steel components exposed to air environments in the auxiliary systems are not susceptible to (halide-induced) loss of material which does not require management. As summarized in item 3.3-1, 006; and 3.3-1, 012 there are select instances where corrosion of stainless steel in air is considered possible and managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP or Bolting Integrity (B.2.3.9) AMP. These include the RMWST tank liner (where contaminants could concentrate in the air-space that is vented to the outdoors, closure bolting (due to potential for local leakage) and insulation jacketing of components located outdoors (per LR-ISG-2012-02). Additionally, as summarized in item 3.3-1, 081 (per LR-ISG-2012-01), aluminum insulation jacketing is also susceptible to a loss of material and managed by the same AMP. Furthermore, as summarized in item 3.5-1, 093, stainless steel structural components located outdoors in above-grade areas prone to frequent or prolonged wetting are susceptible to corrosion that is managed by the Structures Monitoring (B.2.3.34) AMP.

3.3.2.2.6. <u>Quality Assurance for Aging Management of Nonsafety-Related Components</u>

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2, of this SRP-LR.)

QA provisions applicable to LR are discussed in Section B.1.3.

3.3.2.2.7. <u>Ongoing Review of Operating Experience (Per LR-ISG-2011-05)</u>

Acceptance criteria are described in Appendix A.4, “Operating Experience for Aging Management Programs.”

The OE process and acceptance criteria are described in Section B.1.4.

3.3.2.2.8. <u>Loss of Material due to Recurring Internal corrosion (Per LR-ISG-2012-02)</u>

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component *either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness).*

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, and (e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.

The CPNPP CAP tracks and trends recurring issues, EOC, and includes recommendations to prevent recurrence, where appropriate. Corrosion in the SSW meets the criteria to be considered RIC based solely on number of instances. However, no minimum wall thickness criteria were exceeded. Reduction in wall thickness has been monitored at a frequency to sufficiently identify any issues. Based on the monitoring, the CPNPP SSW does not meet criteria for extent of degradation. Therefore, as summarized in item 3.3-1, 127, RIC is not an applicable aging effect for metals in CPNPP Auxiliary systems containing raw water, waste water or treated water. As such, credited CPNPP AMPs, such as the Fire Water System (B.2.3.16) AMP, Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP, and the Open-Cycle Cooling Water System (B.2.3.11) AMP, do not require enhancements to address RIC in Auxiliary systems.

3.3.2.3. Time-Limited Aging Analysis

The TLAAs identified below are associated with the Auxiliary Systems:

- Section 4.3, “Metal Fatigue”
- Section 4.7.4, “Crane Load Cycle Limits”

3.3.3. Conclusion

The Auxiliary Systems piping, fittings, and components that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the Auxiliary System components are identified in the summaries in Section 3.3.2.1 above.

A description of these AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the PEO.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Auxiliary System components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the PEO.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 001	Steel Cranes: structural girders exposed to Air – indoor, uncontrolled (External)	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation for structural girders of cranes that fall within the scope of 10 CFR 54 (see the SRP, Section 4.7, “Other Plant-Specific Time-Limited Aging Analyses,” for generic guidance for meeting the requirements of 10 CFR 54.21(c)(1))	Yes, TLAA (See SRP subsection 3.3.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage (crane load cycle limits) is an aging effect evaluated by the TLAA in Section 4.7.4 for steel crane/hoist bridges, trolleys, girders, structural members, and bolting exposed to indoor air or to outdoor air. Structural components referencing this item are listed in Table 3.5.2-14. Further evaluation is documented in subsection 3.3.2.2.1.
3.3-1, 002	Stainless steel, Steel Heat exchanger components and tubes, Piping, piping components, and piping elements exposed to Treated borated water, Air - indoor, uncontrolled, Treated water	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 “Metal Fatigue,” for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See SRP subsection 3.3.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect evaluated by the fatigue TLAA in Section 4.3.3 for the CVCS, Process Sampling System, and (Liquid) Waste Processing System. In addition, cumulative fatigue damage of stainless steel portions of the Feedwater System is evaluated by the fatigue TLAA in Section 4.3.3. A plant-specific note is used. Further evaluation is documented in subsection 3.3.2.2.1.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 003	Stainless steel Heat exchanger components, non-regenerative exposed to Treated borated water >60°C (>140°F)	Cracking due to stress corrosion cracking; cyclic loading	Chapter XI.M2, “Water Chemistry” The AMP is to be augmented by verifying the absence of cracking due to stress corrosion cracking and cyclic loading. An acceptable verification program is to include temperature and radioactivity monitoring of the shell side water, and eddy current testing of tubes.	Yes, plant-specific (See SRP subsection 3.3.2.2.2)	Consistent with exception to NUREG-1801. Cracking of stainless steel letdown heat exchanger components exposed to treated borated water >60°C (>140°F) in the CVCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking and augments it relative to cyclic cracking. Further evaluation is documented in subsection 3.3.2.2.2.
3.3-1, 004	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See SRP subsection 3.3.2.2.3)	Not applicable. Air does not contain sufficient halides to make stress corrosion cracking a concern for stainless steel in air. Further evaluation is documented in subsection 3.3.2.2.3.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 005	Steel (with stainless steel or nickel-alloy cladding) Pump Casings exposed to Treated borated water	Loss of material due to cladding breach	A plant-specific aging management program is to be evaluated. Reference NRC IN 94-63, “Boric Acid Corrosion of Charging Pump Casings Caused by Cladding Cracks."	Yes, verify that plant-specific program addresses clad cracking (See SRP subsection 3.3.2.2.4)	Not applicable. The CPNPP charging pumps have solid stainless steel casings, without cladding. Further evaluation is documented in subsection 3.3.2.2.4.
3.3-1, 006	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See SRP subsection 3.3.2.2.5)	Consistent with NUREG-1801 as supplemented by LR-ISG-2012-02. Environmental conditions at CPNPP are such that degradation of stainless steel exposed to outdoor air is not expected, except potentially in locations of water pooling or water inside insulation jacketing. Further evaluation is documented in Section 3.3.2.2.5. In addition, as listed in Table 3.5.2-13, stainless steel insulation jacketing that is located outdoors is conservatively managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Furthermore, stainless steel structural components located outdoors, where frequent or prolonged wetting is possible, are addressed in item 3.5-1, 093.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 007	Stainless steel High-pressure pump, casing exposed to Treated borated water	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD"	No	Consistent with NUREG-1801. The ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD (B.2.3.1) AMP will be used to manage cracking of high-pressure stainless steel charging pumps exposed to treated borated water >60°C (>140°F) in the CVCS.
3.3-1, 008	Stainless steel Heat exchanger components and tubes exposed to Treated borated water >60°C (>140°F)	Cracking due to cyclic loading	Chapter XI.M1, "ASME Section XI Inservice Inspection, Subsections IWB, IWC, and IWD"	No	Not used. Stainless steel heat exchanger components and tubes exposed to treated borated water >60°C (>140°F) in the CVCS are included with item 3.3-1, 020.
3.3-1, 009	Steel, Aluminum, Copper alloy (>15% Zn or >8% Al) External surfaces, Piping, piping components, and piping elements, Bolting exposed to Air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-1801. Loss of material due to boric acid corrosion (BAC) of steel, including cast iron and galvanized steel and copper alloy (>15% Zn or >8% Al) external surfaces, including bolting, in the auxiliary systems is managed by the Boric Acid Corrosion (B.2.3.4) AMP. There are no aluminum components exposed to air with borated water leakage in the auxiliary systems. Aluminum components in the auxiliary systems are limited to the EDG and Auxiliary (Table 3.3.2-5) and Miscellaneous Ventilation Systems (Table 3.3.2-8c) which are not located in the vicinity of borated water systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 010	Steel, high-strength Closure bolting exposed to Air with steam or water leakage	Cracking due to stress corrosion cracking; cyclic loading	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There is no steel, high-strength closure bolting in the auxiliary systems.
3.3-1, 011	Steel, high-strength High-pressure pump, closure bolting exposed to Air with steam or water leakage	Cracking due to stress corrosion cracking; cyclic loading	Chapter XI.M18, "Bolting Integrity"	No	Not applicable. There are no steel, high-strength high-pressure pumps or closure bolting in the auxiliary systems.
3.3-1, 012	Steel; stainless steel Closure bolting, Bolting exposed to Condensation, Air – indoor, uncontrolled (External), Air – outdoor (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of material of steel and stainless steel bolting exposed to condensation, indoor air, or outdoor air in the auxiliary systems is managed by the Bolting Integrity (B.2.3.9) AMP. In addition, as listed in Table 3.3.2-12, bolting for SSW pump columns are the same material as the pump columns (copper alloy >15% Zn or >8% Al) and exposed to condensation above the waterline in the bay and loss of material is managed by the Bolting Integrity (B.2.3.9) AMP.
3.3-1, 013	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity"	No	Not used. Loss of material of steel closure bolting in the auxiliary systems is addressed in item 3.3-1, 012. As described in Table 3.0-1, it is recognized that the leakage at bolted joints may occur in indoor air, outdoor air, or condensation environments.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 014	Steel, Stainless Steel Bolting exposed to Soil	Loss of preload	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of preload of steel and stainless steel bolting exposed to soil in the SSW, EDG and Auxiliary (fuel oil), and Fire Protection Systems is managed by the Bolting Integrity (B.2.3.9) AMP.
3.3-1, 015	Steel; stainless steel, Copper alloy, Nickel alloy, Stainless steel Closure bolting, Bolting exposed to Air – indoor, uncontrolled (External), Any environment, Air – outdoor (External), Raw water, Treated borated water, Fuel oil, Treated water	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity"	No	Consistent with NUREG-1801. Loss of preload of copper alloy (>15% Zn or >8% Al), steel, and stainless steel bolting exposed to air - indoor uncontrolled (external), air - outdoor (external), condensation, and raw water in the auxiliary systems is managed by the Bolting Integrity (B.2.3.9) AMP. There is no nickel alloy closure bolting or bolting in the auxiliary systems.
3.3-1, 016	Not applicable. This line item only applies to BWRs.				

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 017	Stainless steel Heat exchanger tubes exposed to Treated water, Treated borated water	Reduction of heat transfer due to fouling	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2011-01. Reduction of heat transfer of stainless steel heat exchanger tubes exposed to treated borated water in the CVCS and SFS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage reduction of heat transfer. There are no stainless steel heat exchanger tubes with a heat transfer function exposed to treated water in the auxiliary systems. Reduction of heat transfer for stainless steel heat exchanger tubes exposed to closed-cooling water is addressed in item 3.3-1, 050 below.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 018	Stainless steel High-pressure pump, casing, Piping, piping components, and piping elements exposed to Treated borated water >60°C (>140°F), Sodium pentaborate solution >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Cracking of stainless steel high-pressure charging pump casings, associated piping and piping components exposed to treated borated water >60°C (>140°F) in the CVCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes an exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. Cracking of other stainless steel pump casings, piping, and piping components exposed to treated borated water >60°C (>140°F) in the CVCS and SFS is addressed by items 3.3-1, 007 and 3.3-1, 124.
3.3-1, 019	Stainless steel Regenerative heat exchanger components exposed to Treated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not used. The regenerative heat exchanger in the CVCS is included with item 3.3-1, 020.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 020	Stainless steel, Stainless steel; steel with stainless steel cladding Heat exchanger components exposed to Treated borated water >60°C (>140°F), Treated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2011-01. Cracking of stainless steel heat exchanger components exposed to treated borated water >60°C (>140°F) or treated water >60°C (>140°F) in the CVCS is managed by the Water Chemistry (B.2.3.2) AMP, which takes an exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. There are no steel with stainless steel cladding heat exchanger components in the auxiliary systems.

There are no aluminum piping or piping components exposed to treated water in the auxiliary systems.
3.3-1, 024	Not applicable. This line item only applies to BWRs.				
3.3-1, 025	Not applicable. This line item only applies to BWRs.				

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 026	Steel with stainless steel cladding Piping, piping components, and piping elements exposed to Treated water	Loss of material due to pitting and crevice corrosion (only after cladding degradation)	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. There are no steel with stainless steel cladding piping and piping components exposed to treated water in the auxiliary systems.
3.3-1, 027	Not applicable. This line item only applies to BWRs.				
3.3-1, 028	Stainless steel Piping, piping components, and piping elements; tanks exposed to Treated borated water (Primary, oxygen levels controlled) >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry"	No	Not used. Cracking of stainless steel piping and piping components exposed to treated borated water >60°C (>140°F) in the CVCS is included with item 3.3-1, 124 below.
3.3-1, 029	Steel (with stainless steel cladding); stainless steel Piping, piping components, and piping elements exposed to Treated borated water (Primary, oxygen levels controlled)	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry"	No	Not used. Loss of material for stainless steel piping and piping components exposed to treated borated water in the CVCS is included with item 3.3-1, 125 below.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 030	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Changes in material properties due to aggressive chemical attack	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There is no concrete or cementitious material piping and piping components exposed to raw water in the SSW System. However, cement-lined ductile iron piping is present in the FPS and is addressed by items 3.3-1, 064; and 3.3-1, 138.
3.3-1, 030.5	Fiberglass, HDPE Piping, piping components, and piping elements exposed to Raw water (internal)	Cracking, blistering, change in color due to water absorption	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no fiberglass, (High Density Polyethylene) HDPE piping, or piping components exposed to raw water (internal) in the GL 98-13 portion of the SSW System. PVC piping in the non-Generic Letter 89-13 portion of the SSW System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. A generic note G and plant-specific note is used.
3.3-1, 031	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Cracking due to settling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There is no concrete or cementitious material piping and piping components exposed to raw water in the SSW System. However, cement lined ductile iron piping is present in the FPS and is addressed by items 3.3-1, 064; and 3.3-1, 138.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 032	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Raw water	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive chemical attack	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Not applicable. There are no reinforced concrete, asbestos cement piping, or piping components exposed to raw water in the SSW System.
3.3-1, 032.5	Elastomer seals and components exposed to raw water	Hardening and loss of strength due to elastomer degradation; loss of material due to erosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Not applicable. There are no elastomer seals and components exposed to raw water in the SSW System.
3.3-1, 033	Concrete; cementitious material Piping, piping components, and piping elements exposed to Raw Water	Loss of material due to abrasion, cavitation, aggressive chemical attack, and leaching	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Not applicable. There are no concrete or cementitious material piping and piping components exposed to raw water in the SSW System. However, cement-lined ductile iron piping is present in the FPS and is addressed by items 3.3-1, 064; and 3.3-1, 138.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 034	Nickel alloy, Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. Loss of material of nickel alloy piping and piping components exposed to raw water in the SSW is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Loss of material for copper alloy piping components exposed to raw water in the SSW System is addressed by item 3.3-1, 036. Loss of material for copper alloy piping components in other auxiliary piping systems is addressed by item 3.3-1, 064 for the FPS and 3.3-1, 093 for the Potable and Sanitary Water System.
3.3-1, 035	Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not used. Loss of material for copper alloy piping components exposed to raw water in the SSW is addressed by item 3.3-1, 036. Loss of material for copper alloy piping components in other auxiliary piping systems is addressed by item 3.3-1, 064 for the FPS and 3.3-1, 093 for the Potable and Sanitary Water System.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 036	Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. As listed in Table 3.3.2-12, loss of material and fouling of copper alloy pump casings and valve bodies exposed to raw water in the SSW System is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Copper alloy bolting for the columns exposed to raw water has loss of material managed by the Bolting Integrity (B.2.3.9) AMP. A generic note E and a plant-specific note are used. Similarly, as listed in Table 3.5.2-13, loss of material for copper alloy structural bolting exposed to a raw water environment in the bay is managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP, which takes an exception. A generic note E and a plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 037	Steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Consistent with NUREG-1801 as supplemented by LR-ISG-2013-01. Loss of material and fouling of steel piping and piping components exposed to raw water in the SSW and EDG and Auxiliary Systems is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Loss of material for non-GL 89-13 steel piping and piping components exposed to raw water in the auxiliary systems is addressed by item 3.3-1, 064 and 3.3-1, 088.
3.3-1, 038	Copper alloy, Steel Heat exchanger components exposed to Raw water	Loss of material due to general, pitting, crevice, galvanic, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Consistent with NUREG-1801. Loss of material and fouling of copper alloy and steel heat exchanger components supplied with raw water from the SSW System are managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. These include – • SI pump lube oil coolers, • Centrifugal charging pump oil coolers, • Component cooling water heat exchangers, and • EDG jacket water coolers. In addition, loss of coating / lining integrity of the EDG jacket water cooler channel head is also addressed in item 3.3-1, 138.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 039	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Not used. Loss of material of stainless steel piping and piping components exposed to raw water in the SSW is addressed in item 3.3-1, 040 below.
3.3-1, 040	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion; fouling that leads to corrosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Consistent with NUREG-1801. Loss of material and fouling of stainless steel piping and piping components exposed to raw water in the SSW is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Loss of material and fouling of stainless steel CCP heat exchanger components exposed to raw water in the CVCS is also managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Loss of material and fouling of stainless steel non-GL 89-13 portions of the auxiliary systems exposed to raw water are addressed in item 3.3-1, 088, (per LR-ISG-2012-02) and 3.3-1, 066.
3.3-1, 041	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, “Open-Cycle Cooling Water System”	No	Not used. As listed in Table 3.3.2-5, there are no stainless steel piping or piping components exposed to raw water in the EDG and Auxiliary Systems. Loss of material of stainless steel piping, and piping components exposed to raw water in other auxiliary systems is addressed by item 3.3-1, 040.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 042	Copper alloy, Titanium, Stainless steel Heat exchanger tubes exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Consistent with NUREG-1801. Reduction of heat transfer of copper alloy heat exchanger tubes exposed to raw water in the centrifugal charging pump oil cooler, CCW heat exchanger, and EDG jacket water heat exchanger, as well as in the stainless steel SSW pump motor bearing cooler is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. Reduction of heat transfer of copper alloy heat exchanger tubes exposed to raw water in the ESF SI pump oil cooler is also managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. There are no titanium heat exchanger tubes exposed to raw water in the auxiliary systems. Reduction of heat transfer for stainless steel ESF containment spray pump oil cooler tubes, supplied by the SSW, is addressed in item 3.2-1, 027.
3.3-1, 043	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Cracking of stainless steel piping and piping components exposed to closed-cycle cooling water >60°C (>140°F) in the CVCS and EDG and Auxiliary Systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 044	Stainless steel; steel with stainless steel cladding Heat Exchanger components exposed to Closed-cycle cooling water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Cracking of stainless steel heat exchanger components exposed to closed-cycle cooling water >60°C (>140°F) in the CVCS is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. There are no steel with stainless steel cladding heat exchanger components exposed to closed-cycle cooling water >60°C (>140°F) in the auxiliary systems.
3.3-1, 045	Steel Piping, piping components, and piping elements; tanks exposed to Closed-cycle cooling water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of steel, including cast iron, piping and piping components and tanks exposed to closed-cycle cooling water in the auxiliary systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 046	Steel, Copper alloy Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, “Closed Treated Water Systems”	No	Consistent with exception to NUREG-1801. Loss of material of steel and copper alloy heat exchanger components, cooling/fan coil unit components, piping, and piping components exposed to closed-cycle cooling water in the auxiliary systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801.
3.3-1, 047	Not applicable. This line item only applies to BWRs.				
3.3-1, 048	Aluminum Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, “Closed Treated Water Systems”	No	Not applicable. There are no aluminum piping or piping components exposed to closed-cycle cooling water in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 049	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Loss of material of stainless steel piping and piping components, as well as stainless steel heat exchanger components and tanks, exposed to closed-cycle cooling water in the auxiliary systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. As listed in Table 3.4.2-4f, loss of material for the stainless steel heat exchanger, piping, and piping components in the Turbine Plant Cooling Water System are also managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 050	Stainless steel, Copper Alloy, Steel Heat exchanger tubes exposed to Closed-cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Consistent with exception to NUREG-1801. Reduction of heat transfer of stainless steel and copper alloy heat exchanger tubes/coils exposed to closed-cycle cooling water in the auxiliary systems is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. Reduction of heat transfer for the cast iron turbocharger casing exposed to closed-cycle cooling water in the EDG and Auxiliary Systems is also managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. There are no other steel heat exchanger tubes or coil components with a heat transfer function in the auxiliary systems.
3.3-1, 051	Boraflex Spent fuel storage racks: neutron-absorbing sheets (PWR), Spent fuel storage racks: neutron-absorbing sheets (BWR) exposed to Treated borated water, Treated water	Reduction of neutron-absorbing capacity due to boraflex degradation	Chapter XI.M22, "Boraflex Monitoring"	No	Not applicable. There are no Boraflex neutron-absorbing sheets at CPNPP. BORAL neutron-absorbing sheets are used and are addressed in item 3.3-1, 102 below.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 052	Steel Cranes: rails and structural girders exposed to Air – indoor, uncontrolled (External)	Loss of material due to general corrosion	Chapter XI.M23, "Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems"	No	Consistent with NUREG-1801. Loss of material for steel crane bridges/trolleys/girders is managed by the Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.3.13) AMP. As listed in Table 3.5.2-14, the majority of the crane components are exposed to air – indoor uncontrolled. Some are located outdoors, and a plant-specific note is used.
3.3-1, 053	Steel Cranes – rails exposed to Air – indoor, uncontrolled (External)	Loss of material due to wear	Chapter XI.M23, "Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems"	No	Not used. Loss of material for crane rails is included in item 3.3-1, 052 above.
3.3-1, 054	Copper alloy Piping, piping components, and piping elements exposed to Condensation	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M24, "Compressed Air Monitoring"	No	Not used. The Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the compressed air remains dry in item 3.3-1, 114 below. Generic note E and plant-specific note is used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 055	Steel Piping, piping components, and piping elements: compressed air system exposed to Condensation (Internal)	Loss of material due to general and pitting corrosion	Chapter XI.M24, “Compressed Air Monitoring”	No	Not used. As listed in Table 3.3.2-8c, the Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the compressed air remains dry in item 3.3-1, 121 below. Generic note E and a plant-specific note are used. In addition, as listed in Table 3.3.2-3, loss of material for steel piping and piping components in the Compressed Air and Plant Gas Systems (that are normally empty or upstream of air dryers and exposed to an air indoor – uncontrolled environment) are included in item 3.2-1, 044.
3.3-1, 056	Stainless steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M24, “Compressed Air Monitoring”	No	Not used. The Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the compressed air remains dry in item 3.3-1, 120 below. Generic note E and a plant-specific note are used.
3.3-1, 057	Elastomers Fire barrier penetration seals exposed to Air – indoor, uncontrolled, Air – outdoor	Increased hardness; shrinkage; loss of strength due to weathering	Chapter XI.M26, “Fire Protection”	No	Consistent with NUREG-1801. As listed in Table 3.5.2-15, hardening and loss of strength of elastomer fire barrier penetration seals is managed by the Fire Protection (B.2.3.15) AMP.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 058	Steel Halon/carbon dioxide fire suppression system piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M26, “Fire Protection”	No	Consistent with NUREG-1801. As listed in Table 3.3.2-7, loss of material of steel Halon fire suppression system piping, and piping components exposed to air – indoor, uncontrolled is managed by the Fire Protection (B.2.3.15) AMP.
3.3-1, 059	Steel Fire rated doors exposed to Air – indoor, uncontrolled, Air – outdoor	Loss of material due to wear	Chapter XI.M26, “Fire Protection”	No	Consistent with NUREG-1801. As listed in Table 3.5.2-15, loss of material for steel (and galvanized steel) fire barrier doors, as well as cable raceways, hatches, penetration sleeves, wall, floor, ceiling assemblies and hose stations is managed by the Fire Protection (B.2.3.15) AMP.
3.3-1, 060	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air – indoor, uncontrolled	Concrete cracking and spalling due to aggressive chemical attack, and reaction with aggregates	Chapter XI.M26, “Fire Protection,” and Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. As listed in Table 3.5.2-15, cracking of indoor concrete fire barrier hatches, walls, floors, and ceilings is managed by the Fire Protection (B.2.3.15) AMP and Structures Monitoring (B.2.3.34) AMP.
3.3-1, 061	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air – outdoor	Cracking, loss of material due to freeze-thaw, aggressive chemical attack, and reaction with aggregates	Chapter XI.M26, “Fire Protection,” and Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. As listed in Table 3.5.2-15, cracking, and loss of material of outdoor concrete fire barrier hatches, walls, floors, and ceilings are managed by the Fire Protection (B.2.3.15) AMP and Structures Monitoring (B.2.3.34) AMP. As described in Section 3.5.2.2.2.1, cracking, and loss of material due to freeze-thaw is not an AERM at CPNPP.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 062	Reinforced concrete Structural fire barriers: walls, ceilings and floors exposed to Air – indoor, uncontrolled, Air – outdoor	Loss of material due to corrosion of embedded steel	Chapter XI.M26, "Fire Protection," and Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. As listed in Table 3.5.2-15, loss of material of indoor concrete fire barrier hatches, walls, floors, and ceilings is managed by the Fire Protection (B.2.3.15) AMP and Structures Monitoring (B.2.3.34) AMP.
3.3-1, 063	Steel Fire Hydrants exposed to Air – outdoor	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M27, "Fire Water System"	No	Consistent with exception to NUREG-1801. As listed in Table 3.3.2-7, loss of material of steel (cast iron) fire hydrants exposed to air – outdoor in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801.
3.3-1, 064	Steel, Copper alloy Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2012-02. Loss of material, fouling, and flow blockage of steel and copper alloy piping and piping components exposed to raw water in the FPS are managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. This line item is also used for flow blockage of cement lined ductile iron exposed to raw water.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 065	Aluminum Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Not applicable. There are no aluminum piping or piping components exposed to raw water in the FPS.
3.3-1, 066	Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting and crevice corrosion; fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, "Fire Water System"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2012-02. Loss of material, fouling, and flow blockage of stainless steel piping components exposed to raw water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801.
3.3-1, 067	Steel Tanks exposed to Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not used. Loss of material of the steel FWSTs exposed to air – outdoor (external) in the FPS is addressed by item 3.3-1, 136.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 068	Steel Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M30, "Fuel Oil Chemistry", and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Loss of material of steel piping and piping components exposed to fuel oil in the FPS is managed by the Fuel Oil Chemistry (B.2.3.17) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Fuel Oil Chemistry (B.2.3.17) AMP to manage loss of material. Furthermore, loss of material for steel EDG and Auxiliary Systems piping and piping components, as well as tanks containing fuel oil in the EDG and Auxiliary and Fire Protection Systems is addressed in item 3.3-1, 070 below.
3.3-1, 069	Copper alloy Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M30, "Fuel Oil Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. There are no copper alloy piping and piping components exposed to fuel oil in the EDG and Auxiliary Systems and Fire Protection System and no other auxiliary systems exposed to fuel oil.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 070	Steel Piping, piping components, and piping elements; tanks exposed to Fuel oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M30, “Fuel Oil Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801. Loss of material and fouling of steel piping, piping components, and tanks exposed to fuel oil in the EDG and Auxiliary and Fire Protection Systems is managed by the Fuel Oil Chemistry (B.2.3.17) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Fuel Oil Chemistry (B.2.3.17) AMP to manage loss of material and fouling.
3.3-1, 071	Stainless steel, Aluminum Piping, piping components, and piping elements exposed to Fuel oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M30, “Fuel Oil Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801. Loss of material of stainless steel piping and tubing exposed to fuel oil in the EDG and Auxiliary and Fire Protection Systems is managed by the Fuel Oil Chemistry (B.2.3.17) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Fuel Oil Chemistry (B.2.3.17) AMP to manage loss of material. There are no aluminum piping or piping components exposed to fuel oil in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 072	Gray cast iron, Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements, Heat exchanger components exposed to Treated water, Closed-cycle cooling water, Soil, Raw water, Waste water	Loss of material due to selective leaching	Chapter XI.M33, "Selective Leaching"	No	Consistent with NUREG-1801 as supplemented by LR-ISG-2012-02. Selective leaching of gray cast iron, cement-lined ductile iron and copper alloy (>15% Zn or >8% Al) piping, piping components, and heat exchanger components exposed to treated water, closed-cycle cooling water, soil, raw water, and waste water in the auxiliary systems is managed by the Selective Leaching (B.2.3.20) AMP. Furthermore, as listed in Table 3.3.2-12 and Table 3.5.2-13, closure, and support bolting for the SSW pump columns are the same aluminum bronze material as the pumps and are submerged in the SWIS Bay, and susceptible to selective leaching that is managed by the Selective Leaching (B.2.3.20) AMP. A generic note F and a plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 073	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air – outdoor	Changes in material properties due to aggressive chemical attack	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no concrete or cementitious piping, and piping components exposed to air – outdoor in the SSW System or other auxiliary systems. As listed in Table 3.3.2-7, cement-lined ductile iron piping in the FPS is buried in the yard and is not exposed to outdoor air. In addition, the cement lining is internal to the piping and addressed with items 3.3-1, 064; 3.3-1, 072; 3.3-1, 106; 3.3-1, 138; 3.3-1, 139 and 3.3.1-140.
3.3-1, 074	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air – outdoor	Cracking due to settling	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. As described for item 3.3-1, 073, there are no concrete or cementitious piping or piping components exposed to air – outdoor in the auxiliary systems.
3.3-1, 075	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Air – outdoor	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive chemical attack	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no reinforced concrete or asbestos cement piping or piping components exposed to air – outdoor in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 076	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (Internal/External)	Hardening and loss of strength due to elastomer degradation	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. Hardening and loss of strength of elastomers, elastomer seals and components exposed to air – indoor, uncontrolled (internal/external) in the Compressed Air and Gas, EDG and Auxiliary, Fire Protection, and {non-containment) Plant Ventilation Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. In addition, as listed in Table 3.1.2-3, hardening and loss of strength of the elastomer RCP oil lift pot/reservoir exposed to air – indoor, uncontrolled (external) is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Furthermore, the elastomer diaphragm for the Reactor Makeup Water Storage Tank (RMSWT) is not subject to hardening or loss of strength as the interior of the missile-protected concrete tank does not include lighting or direct sunlight. A generic note G and a plant-specific note are used.
3.3-1, 077	Concrete; cementitious material Piping, piping components, and piping elements exposed to Air – outdoor	Loss of material due to abrasion, cavitation, aggressive chemical attack, and leaching	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. As described for item 3.3-1, 073 above, there are no concrete or cementitious piping or piping components exposed to air – outdoor in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 078	Steel Piping and components (External surfaces), Ducting and components (External surfaces), Ducting; closure bolting exposed to Air – indoor, uncontrolled (External), Air – indoor, uncontrolled (External), Air – outdoor (External), Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Consistent with NUREG-1801. Loss of material of the external surfaces of steel (including galvanized steel and cast iron) piping and piping components, ducting, and ducting components, as well as tanks and heat exchanger components exposed to air – indoor, uncontrolled (external), air – outdoor (external), or condensation (external) in the auxiliary systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP.
3.3-1, 079	Copper alloy Piping, piping components, and piping elements exposed to Condensation (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Consistent with NUREG-1801. Loss of material of the copper alloy piping, piping components, and cooling coil/unit components exposed to condensation (external) in the SSW, Ventilation Chilled Water, and Plant Ventilation Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Copper alloy cooling coil fins and cooling coils exposed to condensation (external) in the Containment Ventilation System is also managed under this item by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Generic note E and a plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 080	Steel Heat exchanger components, Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Consistent with NUREG-1801. Loss of material of steel heat exchanger components exposed to air – indoor, uncontrolled (external) in the auxiliary systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Steel intercooler heat exchanger tubesheets exposed to air – indoor uncontrolled (external) in the EDG and Auxiliary Systems is managed under this item by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Generic Note E and a plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 081	Copper alloy, Aluminum Piping, piping components, and piping elements exposed to Air – outdoor (External), Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. The External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP will manage loss of material for the aluminum insulation jacketing commodity on components located outdoors, as listed in Table 3.5.2-13. The copper alloy deluge spray nozzles exposed to outdoor air in the FPS are addressed in item 3.3-1, 131. There are no other copper alloy piping or piping components exposed to outdoor air in the auxiliary systems. Aluminum piping and ducting components exposed to indoor or outdoor air in the EDG and Auxiliary and Miscellaneous Ventilation Systems are addressed in item 3.3-1, 113. A generic note I and a plant-specific note are used for the outdoor air environment.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 082	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (External)	Loss of material due to wear	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. Loss of material of elastomers, elastomer seals and components exposed to air – indoor, uncontrolled (external) in the Compressed Air and Gas, EDG and Auxiliary, Fire Protection, and (non-Containment) Ventilation Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. In addition, as listed in Table 3.1.2-3, loss of material for the elastomer RCP oil lift pot/reservoir exposed to air – indoor, uncontrolled (external) is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. A generic note C and a plant-specific note are used.
3.3-1, 083	Stainless steel Diesel engine exhaust piping, piping components, and piping elements exposed to Diesel exhaust	Cracking due to stress corrosion cracking	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Cracking of stainless steel piping components (expansion joints) exposed to diesel exhaust in the EDG and Auxiliary and Fire Protection Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.3-1, 084	[There is no 3.3-1, 084 in NUREG-1800]				

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 085	Elastomers Elastomer seals and components exposed to Closed-cycle cooling water	Hardening and loss of strength due to elastomer degradation	Chapter XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Not applicable. There are no elastomer components exposed to closed-cycle cooling water in the auxiliary systems.
3.3-1, 086	Elastomers Elastomers, linings, Elastomer: seals and components exposed to Treated borated water, Treated water, Raw water	Hardening and loss of strength due to elastomer degradation	Chapter XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-1801. As listed in Table 3.3.2-4, hardening and loss of strength of elastomer components exposed to treated water in the DRMWS is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. There are no elastomers, elastomer linings or seals exposed to raw water or treated borated water in the auxiliary systems.
3.3-1, 087	[There is no 3.3-1, 087 in NUREG-1800]				

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 088	Steel; stainless steel Piping, piping components, and piping elements, Piping, piping components, and piping elements, diesel engine exhaust exposed to Raw water (potable), Diesel exhaust	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-1801. Loss of material of steel and stainless steel piping and piping components exposed to diesel engine exhaust in the EDG and Auxiliary and Fire Protection Systems or to raw water in the Control Room Ventilation System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Furthermore, reduction of heat transfer for the cast iron turbocharger casing exposed to diesel exhaust is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. A plant-specific note is used. Loss of material for stainless steel piping and piping components exposed to raw water in the Potable and Sanitary Water System is also managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. As listed in Table 3.3.2-9b, there are no steel piping or piping components in the Potable and Sanitary Water System.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 089	Steel, Copper alloy Piping, piping components, and piping elements exposed to Moist air or condensation (Internal)	Loss of material due to general, pitting, and crevice corrosion	For fire water system components: Chapter XI.M27, "Fire Water System," or for other components: Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801 as supplemented by LR-ISG-2012-02. Loss of material of steel piping and piping components exposed to condensation (internal), which includes moist air as defined in Table 3.0-1, in the EDG starting air sub-system is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Copper alloy and steel piping and piping components exposed to condensation (internal) or to uncontrolled indoor air in the FPS is addressed by item 3.3-1, 131.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 090	Steel Ducting and components (Internal surfaces) exposed to Condensation (Internal)	Loss of material due to general, pitting, crevice, and (for drip pans and drain lines) microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material for steel and galvanized steel drip pans exposed to condensation (internal) in the Control Room, Miscellaneous, and Primary Plant Ventilation Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Furthermore, condensation entering drain lines (piping) is considered waste water and loss of material is addressed in item 3.3-1, 091. As listed in Tables 3.3.2-8a, and 3.3.2-8c, drip pans in the Containment Ventilation System and for the Uninterruptible Power Supply coolers in are stainless steel and, therefore, are addressed in item 3.3-1, 094.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 091	Steel Piping, piping components, and piping elements; tanks exposed to Waste Water	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material of steel piping, piping components, and tanks exposed to waste water in the CVCS, EDG and Auxiliary Systems, FPS (RCS oil spillage), and Ventilation System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. As listed in Table 3.4.2-4c, loss of material of steel piping and piping components exposed to waste water in the CPS is also managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.3-1, 092	Aluminum Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no aluminum piping or piping components exposed to condensation (internal) in the auxiliary systems. As listed in Table 3.3.2-5, the aluminum casing of the crankcase blower in the EDG and Auxiliary Systems is exposed to waste water and loss of material is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. A generic note G and plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 093	Copper alloy Piping, piping components, and piping elements exposed to Raw water (potable)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material of copper alloy piping (tubing) components exposed to raw water (potable) in the Potable and Sanitary Water System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.3-1, 094	Stainless steel Ducting and components exposed to Condensation	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material for stainless steel cooling coil headers and drip pans in the Containment Ventilation Systems and stainless steel drip pan in the Miscellaneous Ventilation Systems exposed to condensation (internal) environment is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. In addition, loss of material for stainless steel piping and piping components in the EDG starting air subsystem is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 095	Copper alloy, Stainless steel, Nickel alloy, Steel Piping, piping components, and piping elements, Heat exchanger components, Piping, piping components, and piping elements; tanks exposed to Waste water, Condensation (Internal)	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material of stainless steel, and steel piping and piping components, heat exchanger components, and tanks exposed to waste water and condensation (internal) in the Equipment and Floor Drain and Waste Processing Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. There are no nickel alloy piping or piping components, heat exchanger components, or tanks exposed to waste water and condensation (internal) in the auxiliary systems. In addition, as listed in Table 3.4.2-3, loss of material for stainless steel piping, piping components and tanks in the Steam Generator blowdown portion of the Main Steam, Reheat and Steam Dump System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 096	Elastomers Elastomer: seals and components exposed to Air – indoor, uncontrolled (Internal)	Loss of material due to wear	Chapter XI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-1801. Loss of material of elastomer components exposed to air – indoor, uncontrolled (internal) in the EDG and Auxiliary and Plant Ventilation Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.3-1, 097	Steel Piping, piping components, and piping elements, Reactor coolant pump oil collection system: tanks, Reactor coolant pump oil collection system: piping, tubing, valve bodies exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, “Lubricating Oil Analysis,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of steel piping, piping components, and tanks exposed to lubricating oil in the CVCS, EDG and Auxiliary Systems (Lubricating Oil), and Control Room Ventilation System, as well as the RCP oil lift components (as listed in Table 3.1.2-3), is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material. As listed in Table 3.3.2-7, RCS oil spillage collection sub-system (RCS OSPS) components are considered to contain waste water. Accordingly, the steel RCS OSPS piping, piping components and tanks are included with item 3.3-1, 091.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 098	Steel Heat exchanger components exposed to Lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M39, “Lubricating Oil Analysis,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of steel heat exchanger components exposed to lubricating oil in the CVCS, Chilled Water System, and EDG and Auxiliary Systems is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material. In addition, as listed in Table 3.1.2-3, loss of material for the steel RCP bearing oil cooler shell is also managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 099	Copper alloy, Aluminum Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. Loss of material of copper alloy piping and piping components exposed to lubricating oil in the Control Room Ventilation System, as well as copper alloy heat exchanger tubes in the CVCS, and EDG and Auxiliary Systems, is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material. There are no aluminum piping or piping components exposed to lubricating oil in the auxiliary systems.
3.3-1, 100	Stainless steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with NUREG-1801. Loss of material of stainless steel piping, piping components, and piping elements (sight glass frame), as well as stainless steel heat exchanger components, exposed to lubricating oil in the CVCS, EDG and Auxiliary Systems, SSW System, and Control Room Ventilation System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 101	Aluminum Heat exchanger tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, “Lubricating Oil Analysis,” and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no aluminum heat exchanger tubes exposed to lubricating oil in the auxiliary systems.
3.3-1, 102	Boral®; boron steel, and other materials (excluding Boraflex) Spent fuel storage racks: neutron-absorbing sheets (PWR), Spent fuel storage racks: neutron-absorbing sheets (BWR) exposed to Treated borated water, Treated water	Reduction of neutron-absorbing capacity; change in dimensions and loss of material due to effects of“ SFP environment	Chapter XI.M40, “Monitoring of Neutron-Absorbing Materials other than Boraflex”	No	Consistent with NUREG-1801. As listed in Table 3.5.2-5, reduction of neutron-absorbing capacity, change in dimensions, and loss of material of Boral® spent fuel storage rack neutron-absorbing sheets exposed to treated borated water is managed by the Monitoring of Neutron-Absorbing Materials Other than Boraflex (B.2.3.26) AMP.
3.3-1, 103	Reinforced concrete, asbestos cement Piping, piping components, and piping elements exposed to Soil or concrete	Cracking due to aggressive chemical attack and leaching; Changes in material properties due to aggressive“ chemical attack	Chapter XI.M41, “Buried” and Underground Piping and Tanks”	No	Not applicable. There are no reinforced concrete or asbestos cement piping and piping components exposed to soil or concrete in the auxiliary systems.
3.3-1, 104	HDPE, Fiberglass Piping, piping components, and piping elements exposed to Soil or concrete	Cracking, blistering, change in color due to water absorption	Chapter XI.M41, “Buried” and Underground Piping and Tanks”	No	Not applicable. There are no HDPE or fiberglass piping or piping components exposed to soil or concrete in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 105	Concrete cylinder piping, Asbestos cement pipe Piping, piping components, and piping elements exposed to Soil or concrete	Cracking, spalling, corrosion of rebar due to "exposure of rebar	Chapter XI.M41, "Buried" and Underground Piping and Tanks"	No	Not applicable. There are no concrete cylinder piping, asbestos cement piping, or piping components exposed to soil or concrete in the auxiliary systems.
3.3-1, 106	Steel (with coating or wrapping) Piping, piping components, and piping elements exposed to Soil or concrete	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried" and Underground Piping and Tanks"	No	Consistent with exception to NUREG-1801. Loss of material of steel (with coating or wrapping) piping and piping components, as well as storage tanks, exposed to soil in the EDG and Auxiliary Systems (Fuel Oil), FPS, and SSW System is managed by the Buried and Underground Piping and Tanks (B.2.3.27) AMP, which takes exception to NUREG-1801. Steel piping exposed to concrete in the FPS is included in item 3.3-1, 120. Additionally, as listed in Tables 3.5.2-5 and 3.5.2-8, below grade piping penetrations for the FB and SWIS have coated steel plate collars exposed to soil that are managed by the Structures Monitoring (B.2.3.34) AMP, which includes inspection of inaccessible components when excavated for other reasons. A generic note E and plant-specific note are used."

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 107	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to Soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, “Buried” and Underground Piping and Tanks”	No	Not used. Stainless steel piping exposed to concrete in the DRMWS, Process and Effluent Radiation Monitoring and Sampling System, and SFS is addressed in item 3.3-1, 120, along with the stainless steel liner of the concrete RMWST. There are no nickel alloy piping or piping components exposed to soil or concrete in the auxiliary systems.
3.3-1, 108	Titanium, super austenitic, aluminum, copper alloy, stainless steel, nickel alloy piping, piping components, and piping elements, bolting exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, “Buried” and Underground Piping and Tanks”	No	Not used. Loss of material of stainless steel piping and piping components exposed to concrete in the DRMWS, Process and Effluent Radiation Monitoring and Sampling System, and SFS is addressed in item 3.3-1, 120, along with the stainless steel liner of the concrete RMWST. There is no titanium, super austenitic, aluminum, copper alloy, or nickel alloy piping or piping component bolting exposed to soil or concrete in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 109	Steel Bolting exposed to Soil or concrete	Loss of material due to general, pitting and crevice corrosion	Chapter XI.M41, "Buried" and Underground Piping and Tanks"	No	Consistent with exception to NUREG-1801. Loss of material of steel bolting exposed to soil in the EDG and Auxiliary Systems (Fuel Oil), FPS, and SSW System is managed by the Buried and Underground Piping and Tanks (B.2.3.27) AMP, which takes exception to NUREG-1801. There is no steel bolting exposed to concrete in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 109.5	Underground aluminum, copper alloy, stainless steel, nickel alloy steel piping, piping components, and piping elements	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground aluminum, copper alloy, stainless steel, steel piping or piping components in the auxiliary systems, with the underground environment defined in Table 3.0-1. Also, as described in Section 2.4.11, the tunnel to the Seismic Category I RMWST is accessible and considered to be a separate room in the Safeguards Building and assigned an air – indoor uncontrolled environment. As described in Section 2.4.5, the same is true of the service water tunnel that passes through the shared FB. Furthermore, as listed in Table 3.3.2-5, piping, and piping components associated with the EDG fuel oil storage tanks are exposed to indoor or outdoor air and are not located in an underground vault.
3.3-1, 110	Not applicable. This line item only applies to BWRs.				
3.3-1, 111	Steel Structural steel exposed to Air – indoor, uncontrolled (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Not used. The CPNPP new fuel storage racks are stainless steel and addressed with item 3.3-1, 120. Loss of material of structural steel exposed to indoor air is addressed with item 3.5-1, 077 below.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 112	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided 1) attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and 2) plant OE indicates no degradation of the concrete	No, if conditions are met.	Consistent with NUREG-1801. As listed in Table 3.3.2-7, steel fire protection piping includes piping that is completely encased in concrete and protected from external aging effects. Also, as listed in Table 3.5.2-1, the steel guard pipes for Containment recirculation sump effluent (post-accident) are completely encased in concrete and protected from external aging effects. A plant-specific note is used. In addition - 1) As described in Section 3.5.2.2 Attributes of CPNPP concrete are consistent with ACI 318. 2) Degradation of concrete that would allow exposure of embedded piping to groundwater has not been identified.
3.3-1, 113	Aluminum Piping, piping components, and piping elements exposed to Air – dry (Internal/External), Air indoor, uncontrolled (Internal/External), Air indoor, controlled (External), Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Aluminum fan housings and crankcase vacuum blowers exposed to indoor air in the Miscellaneous Ventilation Systems and EDG and Auxiliary Systems, respectively, are not subject to aging effects. Fans housings are also exposed to outdoor air. A generic note I and plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 114	Copper alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External), Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Copper alloy components exposed to indoor air or gas in the auxiliary systems are not subject to aging effects. In addition, as listed in Table 3.3.2-3, the Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the air remains dry, such that copper alloy components exposed to the environment are not subject to aging. A generic note E and plant-specific note are used.
3.3-1, 115	Copper alloy (≤15% Zn and ≤8% Al) Piping, piping components, and piping elements exposed to Air with borated water leakage	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
3.3-1, 116	Galvanized steel Piping, piping components, and piping elements exposed to Air - indoor, uncontrolled	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 117	Glass Piping elements exposed to Air – indoor, uncontrolled (External), Lubricating oil, Closed-cycle cooling water, Air – outdoor, Fuel oil, Raw water, Treated water, Treated borated water, Air with borated water leakage, Condensation (Internal/External) Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
3.3-1, 118	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
3.3-1, 119	Nickel alloy, PVC, Glass Piping, piping components, and piping elements exposed to Air with borated water leakage, Air – indoor, uncontrolled, Condensation (Internal), Waste Water	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 120	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (Internal/External), Air – indoor, uncontrolled (External), Air with borated water leakage, Concrete, Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. Also includes stainless steel ducting components, heat exchanger components, and tanks, as well as stainless steel new fuel storage racks and doors in Section 3.5.2. Furthermore, as listed in Table 3.4.2-3, also includes stainless steel components exposed to air with borated water leakage in the Main Steam, Reheat and Steam Dump systems. In addition, as listed in Tables 3.3.2-3 and 3.4.2-1, the Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the air remains dry, such that stainless steel components exposed to the environment in the Compressed Air and Plant Gas and Auxiliary Feedwater Systems are not susceptible to aging degradation. A generic note E and plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 121	Steel Piping, piping components, and piping elements exposed to Air – indoor, controlled (External), Air – dry, Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801. As listed in Table 3.2.2-5, also includes carbon steel components exposed to gas in the SIS. In addition, as listed in Tables 3.3.2-8c and 3.4.2-1, the Compressed Air Monitoring (B.2.3.14) AMP is credited with ensuring the air remains dry, such that carbon steel components exposed to a dry air environment in the Miscellaneous Ventilation Systems and AFWS, respectively, are not susceptible to aging degradation. A generic note E and plant-specific note are used.
3.3-1, 122	Titanium Heat exchanger components, Piping, piping components, and piping elements exposed to Air – indoor, uncontrol–ed or Air – outdoor	None	None	NA - No AEM or AMP	Not applicable. There are no titanium heat exchanger components, piping, or piping components exposed to air – indoor, uncontrolled or air – outdoor in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 123	Titanium (ASTM Grades 1,2, 7, 11, or 12 that contains > 5% aluminum or more than 0.20% oxygen or any amount of tin) Heat exchanger components other than tubes, Piping, piping components, and piping elements exposed to raw water	None	None	NA - No AEM or AMP	Not applicable. There are no titanium (ASTM grades 1,2, 7, 11, or 12 that contains > 5% aluminum or more than 0.20% oxygen or any amount of tin) heat exchanger components, piping, or piping components exposed to raw water in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 124	Stainless steel, Steel (with stainless steel or nickel-alloy cladding) Spent fuel storage racks (BWR), Spent fuel storage racks (PWR), Piping, piping components, and piping elements; exposed to Treated water >60°C (>140°F), Treated borated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2011-01. Cracking of stainless steel piping, piping components, as well as heat exchanger components and tanks exposed to treated borated water >60°C (>140°F) in the CVCS, Process and Effluent Radiation Monitoring and Sampling System, and SFS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. Cracking of stainless steel spent fuel storage racks, as listed in Table 3.5.2-5, is also managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. A plant-specific note is used. There are no spent fuel storage racks (BWR) at CPNPP. There are no steel (with stainless steel or nickel alloy cladding) spent fuel storage racks (PWR) at CPNPP.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 125	Steel (with stainless steel cladding); stainless steel Spent fuel storage racks (BWR), Spent fuel storage racks (PWR), Piping, piping components, and piping elements exposed to Treated Water, Treated borated water	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2011-01. Loss of material of stainless steel piping, and piping components, as well as heat exchanger components and tank exposed to treated borated water in the CVCS, Process and Effluent Radiation Monitoring and Sampling System, and SFS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of stainless steel spent fuel storage racks, as listed in Table 3.5.2-5, is also managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. There are no spent fuel storage racks (BWR), or Steel (with stainless steel cladding) spent fuel storage racks (PWR), piping, or piping components exposed to treated water or treated borated water in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 126	Any material, piping, piping components, and piping elements exposed to treated water, treated water (borated), raw water	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2012-01. Wall thinning (due to erosion) of carbon steel, cast iron, copper alloy, and stainless steel piping exposed to closed-cycle cooling water, raw water, treated water, or treated borated water in the CVCS, CCW System, Demineralized and Reactor Water Makeup System, and Process Effluent Radiation Monitoring and Sampling System, as well as in the NNS portions of the SSW System is managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801. As listed in Table 3.2.2-5, for heat exchanger components exposed to raw water in the SIS, wall thinning (due to erosion) is also managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801. As listed in Table 3.3.2-12, wall thinning (loss of material) of steel and stainless steel piping exposed to raw water in the nuclear safety related portions of the SSW System is managed by the Open-Cycle Cooling Water System (B.2.3.11) AMP. A Generic Note E and a plant-specific note are used.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems					
Item Number	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.3-1, 127	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See SRP Subsection 3.3.2.2.8)	Not applicable. Loss of material due to recurring internal corrosion has not been identified in metallic piping, piping components, and tanks exposed to raw water or waste water in the auxiliary systems. Further evaluation is documented in subsection 3.3.2.2.8.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 128	Steel, stainless steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil or concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, or crevice corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not used. Other than the RMWSTs, FOSTs, and FWSTs, metallic tanks in the auxiliary systems are located indoors and not exposed to soil or concrete. Also, tank capacities are less than 100,000 gallons. As described in Section 2.4.11, the RMWST in the Demineralized and Reactor Water Makeup System is a reinforced concrete tank. Aging management review of the concrete is listed in Table 3.5.2-11. As described in Section 2.3.3.5, the carbon steel FOST is buried in soil. Loss of material for the surface exposed to soil is addressed in item 3.3-1, 106. As described in Section 2.3.3.7, the carbon steel FWST in the FPS is located outdoors. Loss of material for the steel exposed to outdoor air is addressed in item 3.3-1, 136 below. In addition, the Fire Water System (B.2.3.16) AMP includes enhancement to address the steel/concrete interface. Therefore, there are no CPNPP tanks in the auxiliary systems that fit the scope of NUREG-1801, AMP XI.M29, Aboveground Metallic Tanks, as supplemented by LR-ISG-2012-02.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 129	Steel tanks exposed to soil or concrete; air-indoor uncontrolled, raw water, treated water, waste water, condensation	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, “Aboveground Metallic Tanks”	No	Not applicable. As discussed for item 3.3-1, 128, there are no CPNPP Tanks in the scope of NUREG-1801, AMP XI.M29, Aboveground Metallic Tanks, as supplemented by LR-ISG-2012-02.
3.3-1, 130	Metallic sprinklers exposed to air-indoor controlled, air-indoor uncontrolled, air-outdoor, moist air, condensation, raw water, treated water	Loss of material due to general (where applicable), pitting, crevice, and microbiologically-influenced corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, “Fire Water System”	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2012-02. Loss of material, fouling, and flow blockage of metallic sprinklers exposed to air-indoor uncontrolled and treated water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801.
3.3-1, 131	Steel, stainless steel, copper alloy, or aluminum fire water system piping, piping components and piping elements exposed to air-indoor uncontrolled (internal), air-outdoor (internal), or condensation (internal)	Loss of material due to general (steel, and copper alloy only), pitting, crevice, and microbiologically-influenced corrosion, fouling that leads to corrosion; flow blockage due to fouling	Chapter XI.M27, “Fire Water System”	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2012-02. Loss of material, fouling, and flow blockage of carbon steel (including cast iron), copper alloy and stainless steel Fire Water System (B.2.3.16) piping, and piping components exposed to air-indoor, air-outdoor, or condensation in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. There are no aluminum piping or piping components in the FPS.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 132	Insulated steel, stainless steel, copper alloy, aluminum, or copper alloy (> 15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy only), pitting, and crevice corrosion; cracking due to stress corrosion cracking (aluminum, stainless steel and copper alloy“ (>15% Zn) only)	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, “Aboveground Metallic Tanks” (for tanks only)	No	Consistent with NUREG-1801, as supplemented by LR-ISG-2012-02. Cracking and loss of material of insulated copper alloy >15% Zn or >8% Al and stainless steel piping and piping components exposed to condensation in the CCW, Ventilation Chilled Water and SSW Systems or components supplied by them is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Loss of material of insulated steel piping and piping components and heat exchanger component (letdown chiller shell) exposed to condensation or outdoor air in the CVCS, CCW System, FPS, and SSW System or components supplied by them is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP.
3.3-1, 133	Underground HDPE piping, piping components, and piping elements in an air-indoor uncontrolled or condensation (external) environment	Cracking, blistering, change in color due to water absorption	Chapter XI.M41, “Buried and Underground Piping and Tanks”	No	Not applicable. There are no underground HDPE piping or piping components exposed to an air-indoor uncontrolled or condensation (external) environment in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 134	Steel, stainless steel, or copper alloy piping, piping components, and piping elements, and heat exchanger components exposed to a raw water environment (for nonsafety-related components not covered by NRC GL 89-13)	Loss of material due to general (steel and copper alloy only), pitting, crevice, and microbiologically influenced (MIC) corrosion, fouling that leads to corrosion	Chapter XI.MI.M38, “Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components”	No	Consistent with NUREG-1801. Loss of material for carbon steel, and stainless steel; as well as copper alloy; piping and piping components exposed to a raw water environment, in the SSW System, outside of the GL 89-13 scope, is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.3-1, 135	Steel or stainless steel pump casings submerged in a waste water (internal and external) environment	Loss of material due to general (steel only), pitting, crevice, and microbiologically influenced corrosion	Chapter XI.MI.M36, “External Surfaces Monitoring of Mechanical Components”	No	Not applicable. There are no steel or stainless steel pump casings submerged in a waste water environment in the auxiliary systems.
3.3-1, 136	Steel, stainless steel or aluminum fire water storage tanks exposed to air-indoor uncontrolled, air-outdoor, condensation, moist air, raw water, treated water	Loss of material due to general (steel only), pitting, crevice, and microbiologically-influenced corrosion, fouling that leads to corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M27, "Fire Water System"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2012-02. Loss of material and fouling of steel FWSTs exposed to air-outdoor and treated water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. Loss of material, cracking, and fouling of stainless steel piping and piping components exposed to treated water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. There are no aluminum tanks in the FPS or other auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 137	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to treated water, treated borated water	Loss of material due to general (steel only) pitting and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not used. As discussed for item 3.3-1, 128 above, there are no CPNPP Tanks in the scope of NUREG-1801, AMP XI.M29, Aboveground Metallic Tanks, as supplemented by LR-ISG-2012-02. The FWST for each unit is exposed to treated water and addressed in item 3.3-1, 136 above. Loss of material for stainless steel tanks exposed to treated borated water in the CVCS and SFS is included with item 3.3-1, 125 above. As listed in Tables 3.3.2-1 and 3.3.2-4, respectively, loss of material for carbon steel and stainless steel tanks, including tank liners, exposed to treated water in the CVCS and Demineralized and Reactor Water Makeup System is included with Steam and Power Conversion tanks in item 3.4-1, 012 below .

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 138	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, waste water, lubricating oil, or fuel oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage, and spalling for cementitious coatings/linings	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2013-01. Loss of coating or lining integrity of metallic piping, piping components, heat exchanger with internal coatings / linings exposed to raw water or treated water in the CCW System, EDG and Auxiliary Systems, SSW System, and FPS is managed by the Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) AMP, which takes exception to NUREG-1801. As listed in Table 3.3.2-7, loss of coating or lining integrity of FWSTs with internal coatings / linings exposed to treated water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. A generic note E and a plant-specific note are used. There are no metallic piping, piping components, heat exchangers, or tanks with internal coatings/linings exposed to closed-cycle cooling water, treated borated water, lubricating oil, or fuel oil in the auxiliary systems.

Table 3.3-1 Summary of Aging Management Programs for Auxiliary Systems

Item Number	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.3-1, 139	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2013-01. Loss of material for metallic piping, piping components, and heat exchanger components with internal coatings / linings exposed to raw water or treated water in the CCW System, EDG and Auxiliary Systems, SSW System, and FPS is managed by the Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) AMP, which takes exception to NUREG-1801.
3.3-1, 140	Gray cast iron piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	No	Consistent with exception to NUREG-1801, as supplemented by LR-ISG-2013-01. The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) AMP is credited to manage loss of material/selective leaching for cement-lined ductile iron exposed to raw water or treated water in the FPS. There are no other cast iron components with internal coatings

Table 3.3.2-1: Chemical and Volume Control System – Summary of Aging Management Evaluation								
Component Type	**Intended Function**	**Material**	**Environment**	**Aging Effect Requiring Management**	**Aging Management Program**	**NUREG-1801 Item**	**Table 1 Item**	**Notes**

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 for material, environment, and aging effect but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Wall thinning due to erosion is applicable to Carbon steel and Stainless steel components exposed to non-borated treated water within the CVCS.
2. NUREG-1801 specifies a plant-specific program to verify the effectiveness of the Water Chemistry (B.2.3.2) program in preventing cracking of the non-regenerative heat exchanger components. The One-Time Inspection (B.2.3.19) program will utilize volumetric inspections to verify the absence of cracking. The Closed Treated Water Systems (B.2.3.12) program includes activities to monitor the radioactivity of the shell side water. Temperature monitoring of shell side is a less sensitive technique and is not used. (Reference Further Evaluation 3.3.2.2.2)
3. Piping associated with the following components have an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4: normal and alternate charging and letdown branch line; normal letdown and excess letdown branch line; pressurizer auxiliary spray line.
4. Structural support functions of moment restraints are managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP and evaluated in Table 3.5.2-13.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

G. Environment not in NUREG-1801 for this component and material

H. Aging effect not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. The Bolting Integrity (B.2.3.9) program will be used to manage this material/environment/aging effect combination.

2. A closed-cycle cooling water environment is not in NUREG-1801 for nickel alloy components. OE from NUREG-2191 (VII.C2.A-471) indicates that nickel alloy components exposed to closed-cycle cooling water experience loss of material and are appropriately managed by the Closed Treated Water Systems (B.2.3.12) AMP.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identified a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. The Compressed Air Monitoring (B.2.3.14) AMP is applied to assure dry-air conditions are maintained during the PEO.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

G. Environment not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. The internal stainless steel liner associated with the RMWST is evaluated in this AMR as a stainless steel tank component type.

2. The external concrete portion of the RMWST is evaluated with the Yard structures in Table 3.5.2-11.

3. The RMWST diaphragm separates the water and air spaces inside the RMWST. RMWST diaphragm membranes are rubber-type material with fiber-reinforcement (i.e. elastomer). Only the loss of material aging effect in the treated water environment requires management since the diaphragm is not exposed directly to UV or heat inside the tank and so is not susceptible to hardening or loss of strength.

4. This item does not require an AMP provided that certain concrete conditions are met. RMWST concrete and associate building wall AMR results are contained in Table 3.5.2-11.

5. Internal and external environment are the same for vent and drain components that are empty downstream of closed valves, such that the condition of external surface is representative of the internal surface condition.

6. Aging effects not applicable, for more information see Sections 3.3.2.2.3 and 3.3.2.2.5.

7. The RMWST is vented to the outdoor air and contaminants/moisture may conservatively collect in the air space above the liner and connected diaphragm.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 material, environment, and aging effect but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) program is used to manage the aging effects for this component, material, and environment combination.
2. The Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) program is used to manage loss of coating integrity for this component, material, and environment combination.
3. Aging effect is consistent with SLR OE presented in NUREG-2191 item VII.I.A-816, further clarified by SLR-ISG-2021-02-MECHANICAL Table 3.3-1 ID 151. Reduction of heat transfer is an applicable aging effect for components with a heat transfer function exposed to an air environment. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) program is used to manage the aging effects as this component is internal to the shell of the heat exchanger.
4. Piping is service water supply and return piping to the jacket water cooler.
5. Reduction of heat transfer is an applicable aging effect for the turbocharger which has a heat transfer function exposed to an air environment (diesel exhaust). The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) program is used to manage the aging effects as the portion of the component exposed to diesel exhaust is internal to the turbocharger.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 material, environment, and aging effect but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. Stainless steel bolting components exposed to waste water are not covered in NUREG-1801. Review of NUREG-2191 shows that these components are addressed (VII.I.AP-124, VII.I.A-426, VII.I.A-423).

2. External surfaces of stainless steel sump pump casings.

Valve body (Halon suppression)	Pressure boundary	Carbon steel	Air – indoor uncontrolled (internal)	Loss of material	Fire Protection (B.2.3.15)	VII.G.AP-150	3.3-1, 058	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identified a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

I. Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.

Plant-Specific Notes

1. The component is located within HVAC housings, and the external surfaces are subject to the HVAC environment of condensation during normal operation.
2. The Fire Water System (B.2.3.16) AMP is substituted for the Water Chemistry (B.2.3.2) AMP and One-Time Inspection (B.2.3.19) AMP.
3. The (Flexible hose – rubber) components for FPS made of Elastomer material subjected to waste water environment is not found in NUREG-1801. Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP will be used to manage these components.
4. The Fire Water System (B.2.3.16) AMP is substituted for the Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks (B.2.3.28) AMP.
5. Stainless steel components in an Air – outdoor (external) environment do not experience aging effects as addressed in LRA Further Evaluation Section 3.3.2.2.6.
6. The submerged bolting components for the FPS made of carbon steel subjected to a raw water environment with a loss of material aging effect is not found in NUREG-1801. OE found in NUREG-2191 (V.E.E-418) indicates that the Bolting Integrity (B.2.3.9) AMP is used to manage loss of material.
7. An emergency fill line is provided from the SWIS to refill the FWSTs with water from the SSI Dam and this portion of the system is exposed to raw water. The remainder of the system is supplied with treated water via the Potable Water System which provides fill and normal makeup to the FWSTs.
8. Consistent with LR-ISG-2012-02, flow blockage due to fouling is an aging effect for cement-lined ductile iron fire protection piping in a raw water environment. The Fire Water System (B.2.3.16) AMP manages this aging effect.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Coils and fins are located inside of air handling and cooling units such that Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) is the credited AMP, in lieu of External Surfaces Monitoring of Mechanical Components (B.2.3.22).

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. Consistent with the latest industry guidance, based on industry OE updates incorporated into NUREG-2191 (Item VII.I.A-716, Table 3.3-1, 151).

2. Consistent with the latest industry guidance, based on industry OE updates incorporated into NUREG-2191 (Item VII.F1.A-495, Table 3.3-1, 159).

3. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.A-504, Table 3.3-1, 085).

4. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.AP-103, Table 3.3-1, 096).

5. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.I.A-720, Table 3.3-1, 150).

6. Galvanized steel components which have the potential to be impacted by adjacent components are treated as carbon steel, due to the possibility of localized corrosion sites.

7. Aging of control room A/C drip pan internal coating/linings is not explicitly managed, only the carbon steel body is integral in maintaining the leakage boundary.

8. Insulated components associated with the control room A/C units operate below the dew point; therefore, these components have the potential to accumulate condensation which may trap particulates underneath insulation.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

I. Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.

Plant-Specific Notes

1. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.A-495, Table 3.3-1, 159).

2. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.D.A-729, Table 3.3-1, 085).

3. Aging of UPS and distribution room A/C drip pan internal coating/linings is not explicitly managed, only the carbon steel body is integral in maintaining the leakage boundary.

4. Galvanized steel components which have the potential to be impacted by adjacent components are treated as carbon steel, due to the possibility of localized corrosion sites.

5. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.A-504, Table 3.3-1, 085).

6. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.AP-103, Table 3.3-1, 096).

7. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.I.A-720, Table 3.3-1, 150).

8. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.I.A-716, Table 3.3-1, 151).

9. Aging effects not applicable, for more information see item Table 3.3-1, item 081.

10. The Compressed Air Monitoring (B.2.3.14) AMP is applied to assure dry-air conditions are maintained during the PEO.

11. Insulated components associated with the UPS room A/C units operate below the dew point; therefore, these components have the potential to accumulate condensation which may trap particulates underneath insulation.

12. Stainless steel drip pans in the Miscellaneous Ventilation Systems are for the UPS room coolers.

Table 3.3.2-8d: Primary Plant Ventilation Systems – Summary of Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect Requiring Management	Aging Management Programs	NUREG-1801 Item	Table 1 Item	Notes
Bolting	Mechanical closure	Carbon steel	Air – indoor uncontrolled (external)	Loss of material	Bolting Integrity (B.2.3.9)	VII.I.AP-125	3.3-1, 012	A
Bolting	Mechanical closure	Carbon steel	Air – indoor uncontrolled (external)	Loss of preload	Bolting Integrity (B.2.3.9)	VII.I.AP-124	3.3-1, 015	A
Bolting	Mechanical closure	Carbon steel	Air – outdoor (external)	Loss of material	Bolting Integrity (B.2.3.9)	VII.I.AP-126	3.3-1, 012	A
Bolting	Mechanical closure	Carbon steel	Air – outdoor (external)	Loss of preload	Bolting Integrity (B.2.3.9)	VII.I.AP-263	3.3-1, 015	A
Bolting	Mechanical closure	Carbon steel	Air with borated water leakage (external)	Loss of material	Boric Acid Corrosion (B.2.3.4)	VII.I.A-102	3.3-1, 009	A
Bolting	Mechanical closure	Stainless steel	Air – indoor uncontrolled (external)	Loss of material	Bolting Integrity (B.2.3.9)	VII.I.AP-125	3.3-1, 012	A
Bolting	Mechanical closure	Stainless steel	Air – indoor uncontrolled (external)	Loss of preload	Bolting Integrity (B.2.3.9)	VII.I.AP-124	3.3-1, 015	A
Bolting	Mechanical closure	Stainless steel	Air – outdoor (external)	Loss of material	Bolting Integrity (B.2.3.9)	VII.I.AP-126	3.3-1, 012	A
Bolting	Mechanical closure	Stainless steel	Air – outdoor (external)	Loss of preload	Bolting Integrity (B.2.3.9)	VII.I.AP-263	3.3-1, 015	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.F1.A-495, Table 3.3-1, 159).

2. Drip pans may include boric acid buildup from beneath the cooling coils.

3. Aging of emergency room cooler drip pan internal coating/linings is not explicitly managed, only the carbon steel body is integral in maintaining the leakage boundary.

4. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.I.A-716, Table 3.3-1, 151).

5. Consistent with the latest industry guidance, based on industry OE updates incorporated in NUREG-2191 (Item VII.I.A-720, Table 3.3-1, 150).

Table 3.3.2-9a: Chlorination System – Summary of Aging Management Evaluation								
Component Type	**Intended Function**	**Material**	**Environment**	**Aging Effect Requiring Management**	**Aging Management Program**	**NUREG-1801 Item**	**Table 1 Item**	**Notes**
Piping	Leakage boundary (spatial)	PVC	Air – indoor uncontrolled (external)	None	None	VII.J.AP-268	3.3-1, 119	A, 1
Piping	Leakage boundary (spatial)	PVC	Air – indoor uncontrolled (internal)	None	None	VII.J.AP-268	3.3-1, 119	A, 1

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

1. Chlorination PVC piping surrounds process tubing and prevents leakage or spray onto nuclear safety related components, should the internal process tubing rupture. For this reason, it has a leakage boundary intended function. However, during normal operation the process tubing is not expected to be ruptured, and therefore the PVC piping is exposed to an internal air – indoor (uncontrolled) environment.

Table 3.3.2-9b: Potable and Sanitary Water System – Summary of Aging Management Evaluation								
Component Type	**Intended Function**	**Material**	**Environment**	**Aging Effect Requiring Management**	**Aging Management Program**	**NUREG-1801 Item**	**Table 1 Item**	**Notes**
Valve body	Leakage boundary (spatial)	Copper alloy >15% Zn or >8% Al	Air – indoor uncontrolled (external)	None	None	VII.J.AP-144	3.3-1, 114	A
Valve body	Leakage boundary (spatial)	Copper alloy >15% Zn or >8% Al	Raw water (internal)	Loss of material	Selective Leaching (B.2.3.20)	VII.C3.A-47	3.3-1, 072	A
Valve body	Leakage boundary (spatial)	Stainless steel	Air – indoor uncontrolled (external)	None	None	VII.J.AP-17	3.3-1, 120	A
Valve body	Leakage boundary (spatial)	Stainless steel	Raw water (internal)	Loss of material	Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)	VII.E5.AP-270	3.3-1, 088	C

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

None.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1800 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

Plant-Specific Notes

1. Piping and tubing associated with the following components have an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4: process sampling – hot leg isolation, process sampling – pressurizer liquid sample isolation.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. The submerged bolting components for the SFS made of stainless steel subjected to a treated borated water environment with a loss of material aging effect is not found in NUREG-1801. OE found in NUREG-2191 (V.E.E-418) indicates that the Bolting Integrity (B.2.3.9) AMP is used to manage loss of material.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. This aging effect is only applicable to components NOT located in the SWIS/Pump house.

2. Closure bolting experiencing loss of preload in a condensation (external) environment is not present in NUREG-1801. OE within NUREG-2191 (VII.I.AP-124) indicates that bolting within any environment can experience loss of preload.

3. Raw water is not in NUREG-1801 for PVC piping. OE within NUREG-2191 (VII.C1.A-787c) indicates that PVC piping (not covered by NRC GL 89-13) within a raw water environment can experience loss of material, which can be properly managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.

4. The Bolting Integrity (B.2.3.9) AMP is credited to manage loss of material of copper alloy closure bolting in a raw water environment.

5. The Open-Cycle Cooling Water AMP is used to manage wall thinning due to erosion for piping covered by NRC GL 89-13.

Valve body	Pressure boundary	Copper alloy >15% Zn or >8% Al	Closed-cycle cooling water (internal)	Loss of material	Closed Treated Water Systems (B.2.3.12)	VII.C2.AP-199	3.3-1, 046	B
Valve body	Pressure boundary	Copper alloy >15% Zn or >8% Al	Closed-cycle cooling water (internal)	Loss of material	Selective Leaching (B.2.3.20)	VII.C2.AP-43	3.3-1, 072	A
Valve body	Pressure boundary	Stainless steel	Air – indoor uncontrolled (external)	None	None	VII.J.AP-123	3.3-1, 120	A
Valve body	Pressure boundary	Stainless steel	Closed-cycle cooling water (internal)	Loss of material	Closed Treated Water Systems (B.2.3.12)	VII.C2.A-52	3.3-1, 049	B
Valve body (insulated)	Leakage boundary (spatial)	Copper alloy >15% Zn or >8% Al	Condensation (external)	Cracking	External Surfaces Monitoring of Mechanical Components (B.2.3.22)	VII.C2.A-405	3.3-1, 132	A
Valve body (insulated)	Leakage boundary (spatial)	Copper alloy >15% Zn or >8% Al	Condensation (external)	Loss of material	External Surfaces Monitoring of Mechanical Components (B.2.3.22)	VII.C2.A-405	3.3-1, 132	A
Valve body (insulated)	Pressure boundary	Copper alloy >15% Zn or >8% Al	Condensation (external)	Cracking	External Surfaces Monitoring of Mechanical Components (B.2.3.22)	VII.C2.A-405	3.3-1, 132	A
Valve body (insulated)	Pressure boundary	Copper alloy >15% Zn or >8% Al	Condensation (external)	Loss of material	External Surfaces Monitoring of Mechanical Components (B.2.3.22)	VII.C2.A-405	3.3-1, 132	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Material not in NUREG-1801 for this component.

Plant-Specific Notes

1. The aging effects for glass components are applied for graphite rupture discs in applicable environments.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

D. Component is different, but consistent with material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

E. Consistent with NUREG-1801 material, environment, and aging effect but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

G. Environment not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. Component downstream of Reactor Coolant Drain Tank Heat Exchanger periodically subjected to temperatures > 140 °F.

2. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP will be used to manage WPS components exposed to steam.

3. NUREG-2191 has been used as guidance to identify the appropriate AMP to manage this material/environment/aging effect combination.

4. Liquid Waste Processing System piping has an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4.

3.4. AGING MANAGEMENT OF STEAM AND POWER CONVERSION SYSTEMS

3.4.1. Introduction

This section provides the results of the AMR for those components identified in Section 2.3.4, "Steam and Power Conversion Systems", as being subject to AMR. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Auxiliary Feedwater System (2.3.4.1)
- Condensate and Feedwater System (2.3.4.2)
- Main Steam, Reheat, and Steam Dump System (2.3.4.3)
- Main Turbine and Auxiliaries System (2.3.4.4)

3.4.2. Results

The following tables summarize the results of the AMR for S&PC Systems.

Table 3.4.2-1: Auxiliary Feedwater System – Summary of Aging Management Evaluation

Table 3.4.2-2: Condensate and Feedwater System – Summary of Aging Management Evaluation

Table 3.4.2-3: Main Steam, Reheat, and Steam Dump System – Summary of Aging Management Evaluation

Table 3.4.2-4a: Auxiliary Steam System – Summary of Aging Management Evaluation

Table 3.4.2-4b: Chemical Feed and Hydrazine Injection – Summary of Aging Management Evaluation

Table 3.4.2-4c: Condensate Polishing System – Summary of Aging Management Evaluation

Table 3.4.2-4d: Condenser Vacuum System – Summary of Aging Management Evaluation

Table 3.4.2-4e: Heater Drain System – Summary of Aging Management Evaluation

Table 3.4.2-4f: Turbine Plant Cooling Water System – Summary of Aging Management Evaluation

3.4.2.1. Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.4.2.1.1. Auxiliary Feedwater System

Materials

The materials of construction for the AFWS components are:

- Carbon steel
- Cast iron
- Stainless steel

Environments

The AFWS components are exposed to the following environments:

- Air – dry
- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Concrete
- Gas
- Lubricating oil
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the AFWS require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Reduction in heat transfer
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the AFWS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Compressed Air Monitoring (B.2.3.14)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

- Lubricating Oil Analysis (B.2.3.25)
- One-Time Inspection (B.2.3.19)
- Selective Leaching (B.2.3.20)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.4.2.1.2. Condensate and Feedwater Systems

Materials

The materials of construction for the Condensate and Feedwater Systems components are:

- Carbon steel
- CASS
- Stainless steel

Environments

The Condensate and Feedwater Systems components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Gas
- Treated water
- Treated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the Condensate and Feedwater Systems require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the Condensate and Feedwater Systems components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)

- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.4.2.1.3. Main Steam, Reheat, and Steam Dump System

Materials

The materials of construction for the MSS components are:

- Carbon steel
- CASS
- Stainless steel

Environments

The MSS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Gas
- Steam
- Treated water
- Treated water > 140°F
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the MSS require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the MSS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- One-Time Inspection (B.2.3.19)

- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

3.4.2.1.4. Main Turbine and Auxiliaries Systems

Auxiliary Steam System

Materials

The materials of construction for the SAS components are:

- Carbon steel
- Cast iron
- Stainless steel

Environments

The SAS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Steam
- Treated water
- Treated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the SAS require management:

- Cracking
- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Wall-thinning

Aging Management Programs

The following AMPs manage the aging effects for the SAS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- Selective Leaching (B.2.3.20)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

Chemical Feed and Hydrazine Injection

Materials

The materials of construction for the CFS and HIS components are:

- Stainless steel

Environments

The CFS and HIS components are exposed to the following environments:

- Air – indoor uncontrolled
- Treated water
- Treated water > 140°F

Aging Effects Requiring Management

The following aging effects associated with the CFS and HIS require management:

- Cracking
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the CFS and HIS components:

- Bolting Integrity (B.2.3.9)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

Condensate Polishing System

Materials

The materials of construction for the CPS components are:

- Carbon steel
- Stainless steel

Environments

The CPS components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Treated water
- Waste water

Aging Effects Requiring Management

The following aging effects associated with the CPS require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the CPS components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)
- One-Time Inspection (B.2.3.19)
- Water Chemistry (B.2.3.2)

Condenser Vacuum System

Materials

The materials of construction for the CVS components are:

- Carbon steel

Environments

The CVS components are exposed to the following environments:

- Air – indoor uncontrolled
- Raw water

Aging Effects Requiring Management

The following aging effects associated with the CVS require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the CVS components:

- Bolting Integrity (B.2.3.9)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24)

Heater Drains System

Materials

The materials of construction for the HDS components are:

- Carbon steel

Environments

The HDS components are exposed to the following environments:

- Air – indoor uncontrolled
- Treated water

Aging Effects Requiring Management

The following aging effects associated with the HDS require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload
- Wall thinning

Aging Management Programs

The following AMPs manage the aging effects for the HDS components:

- Bolting Integrity (B.2.3.9)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Flow-Accelerated Corrosion (B.2.3.8)
- One-Time Inspection (B.2.3.19)
- TLAA (Section 4.3)
- Water Chemistry (B.2.3.2)

Turbine Plant Cooling Water System

Materials

The materials of construction for the TPCW components are:

- Carbon steel
- Stainless steel

Environments

The TPCW components are exposed to the following environments:

- Air – indoor uncontrolled
- Air with borated water leakage
- Closed-cycle cooling water

Aging Effects Requiring Management

The following aging effects associated with the TPCW require management:

- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the TPCW components:

- Bolting Integrity (B.2.3.9)
- Boric Acid Corrosion (B.2.3.4)
- Closed Treated Water Systems (B.2.3.12)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)

3.4.2.2. AMR Results for Which Further Evaluation is Recommended by the GALL Report

The AMR summaries for the S&PC Systems provide the basis for Section 3.4.2.2 and are compiled from Section 3.3.2.1. NUREG-1801 provides the basis for identifying those programs that warrant FE by the reviewer in the LRA. For the S&PC Systems, those programs are addressed in the following sections.

Note – Italicized text is taken directly from NUREG-1800 as supplemented by LR-ISG-2011-05 and LR-ISG-2012-02.

3.4.2.2.1. Cumulative Fatigue Damage

Fatigue is a TLAA as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21I. This TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR. The related GALL Report items invoked by the subsection are VIII.D1.S-11, VIII.D2.S-11, VIII.G.S-11, VIII.B1.S-08, VIII.B2.S-08.

Where identified as an AERM, the analysis of fatigue is a TLAA as defined in 10 CFR 54.3. As summarized in item 3.4-1, 001, TLAAs are evaluated in accordance with 10 CFR 54.21(c). Steam and Power Conversion (S&PC) Systems susceptible to cumulative fatigue damage are MS, Feedwater, Auxiliary Feedwater, Auxiliary Steam, and Heater Drains. Evaluation of this TLAA is addressed in Section 4.3.3.

3.4.2.2.2. Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of cracking also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Cracking is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible.

Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those with½1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above. GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external chloride stress corrosion cracking is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements applicable to the components.

The outdoor environment at CPNPP is described in Section 3.2.2.2.3, item 2 above. As described there, the outdoor air does not contain sufficient halides for degradation of stainless steel components in air. A review of CPNPP OE and evaluation of the location and surroundings of the plant have determined that the air at CPNPP does not contain sufficient halides nor are there events that would likely increase the halide content in the air to make stress corrosion cracking an AERM. As such, as summarized in item 3.4-1, 002, stainless steel components exposed to air environments in the S&PC Systems are not susceptible to SCC and do not require management for SCC except as noted. The CSTs are outdoor reinforced concrete tanks with stainless steel liners as described in Section 2.4.11. As summarized in item 3.4-1, 063 (per LR-ISG-2012-02), SCC of insulated Feedwater System piping located outdoors is considered susceptible to cracking (water through or under insulation) and is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. The CSTs are outdoor reinforced concrete tanks with stainless steel liners as described in Section 2.4.11.

3.4.2.2.3. Loss of Material due to Pitting and Crevice Corrosion

Loss of material due to pitting and crevice corrosion could occur for stainless steel piping, piping components, piping elements, and tanks exposed to outdoor air. The possibility of pitting and crevice corrosion also extends to components exposed to air which has recently been introduced into buildings, i.e., components near intake vents. Pitting and crevice corrosion is only known to occur in environments containing sufficient halides (primarily chlorides) and in which condensation or deliquescence is possible. Condensation or deliquescence should generally be assumed to be possible. Applicable outdoor air environments (and associated indoor air environments) include, but are not limited to, those within approximately 5 miles of a saltwater coastline, those with½1/2 mile of a highway which is treated with salt in the wintertime, those areas in which the soil contains more than trace chlorides, those plants having cooling towers where the water is treated with chlorine or chlorine compounds, and those areas subject to chloride contamination from other agricultural or industrial sources. This item is applicable for the environments described above.

GALL AMP XI.M36, "External Surfaces Monitoring," is an acceptable method to manage the aging effect. The applicant may demonstrate that this item is not applicable by describing the outdoor air environment present at the plant and demonstrating that external pitting or crevice corrosion is not expected. The GALL Report recommends further evaluation to determine whether an adequate aging management program is used to manage this aging effect based on the environmental conditions applicable to the plant and ASME Code Section XI requirements Quality Assurance for Aging Management of Nonsafety-Related Components.

The outdoor environment at CPNPP is described in Section 3.2.2.2.3, item 2 above. As described there, the outdoor air does not contain sufficient halides for degradation of stainless steel components in air. A review of CPNPP OE and evaluation of the location and surroundings of the plant have determined that the air at CPNPP does not contain sufficient halides nor are there events that would likely increase the halide content in the air to make loss of material due to pitting and crevice corrosion an AERM. As such, stainless steel components exposed to air environments in the S&PC Systems are not susceptible to SCC or loss of material and do not require management for SCC or loss of material except as noted. As summarized in items 3.4-1, 003; 3.4-1, 008; and 3.4-1, 063, there are select instances where corrosion of stainless steel in air is considered possible and managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP or Bolting Integrity (B.2.3.9) AMP. These instances include: liner inside the CST (where contaminants could concentrate in the air space that is vented to the outdoors), closure bolting (due to the potential for local leakage), and through or under insulation (per LR-ISG-2012-02).

3.4.2.2.4. Quality Assurance for Aging Management of Nonsafety-Related Components

Acceptance criteria are described in Branch Technical Position IQMB-1 (Appendix A.2, of this SRP-LR).

QA provisions applicable to LR are discussed in Section B.1.3.

3.4.2.2.5. Ongoing Review of Operating Experience (per LR-ISG-2011-05)

Acceptance criteria are described in Appendix A.4, "Operating Experience for Aging Management Programs."

The OE process and acceptance criteria are described in Section B.1.4.

3.4.2.2.6. Loss of Material due to Recurring Internal Corrosion (per LR-ISG-2012-02)

Recurring internal corrosion can result in the need to augment AMPs beyond the recommendations in the GALL Report. During the search of plant-specific OE conducted during the LRA development, recurring internal corrosion can be identified by the number of occurrences of aging effects and the extent of degradation at each localized corrosion site. This further evaluation item is applicable if the search of plant-specific OE reveals repetitive occurrences (e.g., one per refueling outage cycle that has occurred over: (a) three or more sequential or nonsequential cycles for a 10-year OE search, or (b) two or more *sequential or nonsequential cycles for a 5-year OE search) of aging effects with the same aging mechanism in which the aging effect resulted in the component either not meeting plant-specific acceptance criteria or experiencing a reduction in wall thickness greater than 50 percent (regardless of the minimum wall thickness).*

The GALL Report recommends that a plant-specific AMP, or a new or existing AMP, be evaluated for inclusion of augmented requirements to ensure the adequate management of any recurring aging effect(s). Potential augmented requirements include: alternative examination methods (e.g., volumetric versus external visual), augmented inspections (e.g., a greater number of locations, additional locations based on risk insights based on susceptibility to aging effect and consequences of failure, a greater frequency of inspections), and additional trending parameters and decision points where increased inspections would be implemented. Acceptance criteria are described in Appendix A.1, "Aging Management Review – Generic (Branch Technical Position RSLB-1)."

The applicant states: (a) why the program's examination methods will be sufficient to detect the recurring aging effect before affecting the ability of a component to perform its intended function, (b) the basis for the adequacy of augmented or lack of augmented inspections, (c) what parameters will be trended as well as the decision points where increased inspections would be implemented (e.g., the extent of degradation at individual corrosion sites, the rate of degradation change), (d) how inspections of components that are not easily accessed (i.e., buried, underground) will be conducted, aI(e) how leaks in any involved buried or underground components will be identified.

Each plant-specific operating experience example should be evaluated to determine if the chosen AMP should be augmented even if the thresholds for significance of aging effect or frequency of occurrence of aging effect have not been exceeded. For example, during a 10-year search of plant specific operating experience, two instances of 360 degree 30 percent wall loss occurred at copper alloy to steel joints. Neither the significance of the aging effect nor the frequency of occurrence of aging effect threshold has been exceeded. Nevertheless, the operating experience should be evaluated to determine if the AMP that is proposed to manage the aging effect is sufficient (e.g., method of inspection, frequency of inspection, number of inspections) to provide reasonable assurance that the CLB intended functions of the component will be met throughout the period of extended operation. Likewise, the GALL Report AMR items associated with the new FE items only cite raw water and waste water environments because OE indicates that these are the predominant environments associated with recurring internal corrosion; however, if the search of plant-specific OE reveals recurring internal corrosion in other water environments (e.g., treated water), the aging effect should be addressed in a similar manner.

The CPNPP CAP tracks and trends recurring issues, EOC, and includes recommendations to prevent recurrence, where appropriate. Through wall leaks in the Turbine Plant Cooling Water (TPCW) System due to undersized welds are prevalent throughout recent OE. Even though degradation in the TPCW stems from an original installation issue, these through wall leaks at weld locations qualify as RIC, given that degradation in the TPCW can be observed throughout the current operating life of the plant. Due to the low stress conditions within the TPCW, many of these undersized welds will last the life of the plant, while others may need multiple repairs. RIC has not been observed in any of the other in-scope S&PC Systems at CPNPP.

There are currently no mitigative strategies in place for the TPCW, other than corrosion inhibiting water chemistry control of the closed system; therefore, to address RIC in the TPCW the Closed Treated Water Systems (B.2.3.12) AMP will be enhanced to perform representative sample inspections of in-scope TPCW welds during the PEO.

3.4.2.3. Time-Limited Aging Analysis

Systems susceptible to cumulative fatigue damage are MS, Feedwater, Auxiliary Feedwater, Auxiliary Steam, and Heater Drains. Evaluation of this TLAA is addressed in the TLAA identified below:

- Section 4.3.3, “ASME Section III, Class 2 and 3 Allowable Stress Analyses”

3.4.3. Conclusion

The S&PC Systems piping, fittings, and components that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the S&PC Systems components are identified in the summaries in Section 3.4.2.1 above.

A description of these AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the PEO.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the S&PC System components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the PEO.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 001	Steel Piping, piping components, and piping elements exposed to Steam or Treated water	Cumulative fatigue damage due to fatigue	Fatigue is a time-limited aging analysis (TLAA) to be evaluated for the period of extended operation. See the SRP, Section 4.3 “Metal Fatigue,” for acceptable methods for meeting the requirements of 10 CFR 54.21(c)(1).	Yes, TLAA (See subsection 3.4.2.2.1)	Consistent with NUREG-1801. Cumulative fatigue damage is an aging effect addressed by a fatigue TLAA (Section 4.3). Further evaluation is documented in subsection 3.4.2.2.1.
3.4-1, 002	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Cracking due to stress corrosion cracking	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.4.2.2.2)	Not applicable. Air does not contain sufficient halides to make SCC a concern. Further evaluation is documented in subsection 3.4.2.2.2.
3.4-1, 003	Stainless steel Piping, piping components, and piping elements; tanks exposed to Air – outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	Yes, environmental conditions need to be evaluated (See subsection 3.4.2.2.3)	Consistent with NUREG-1801, as clarified. Air does not contain sufficient halides to make loss of material due to pitting and crevice corrosion a concern. A generic note I and plant-specific note are used for vent piping and components inside the concrete CST as listed in Table 3.4.2-1. Loss of material for the top portion of the liner in the concrete CST above the water-line and exposed to outdoor air through vents is manage by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. Further evaluation is documented in subsection 3.4.2.2.3.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 004	Steel External surfaces, Bolting exposed to Air with borated water leakage	Loss of material due to boric acid corrosion	Chapter XI.M10, "Boric Acid Corrosion"	No	Consistent with NUREG-1801. Loss of material of steel external surfaces and bolting exposed to air with borated water leakage in the S&PC Systems is managed by the Boric Acid Corrosion (B.2.3.4) AMP.
3.4-1, 005	Steel Piping, piping components, and piping elements exposed to Steam, Treated water	Wall thinning due to flow-accelerated corrosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with exception to NUREG-1801. Wall thinning of steel piping and piping components exposed to treated water, including steam, in the S&PC Systems is managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801.
3.4-1, 006	Steel, Stainless Steel Bolting exposed to Soil	Loss of preload	Chapter XI.M18, "Bolting Integrity "	No	Not applicable. There are no steel or stainless steel bolting exposed to soil in the S&PC Systems.
3.4-1, 007	High-strength steel Closure bolting exposed to Air with steam or water leakage	Cracking due to cyclic loading, stress corrosion cracking	Chapter XI.M18, "Bolting Integrity "	No	Not applicable. There are no high strength steel closure bolting exposed to air with steam or water leakage in the S&PC Systems.
3.4-1, 008	Steel; stainless steel Bolting, Closure bolting exposed to Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M18, "Bolting Integrity "	No	Consistent with NUREG-1801. Loss of material of steel and stainless steel bolting exposed to air – indoor, uncontrolled (external) in the S&PC Systems is managed by the Bolting Integrity (B.2.3.9) AMP. Loss of material of steel bolting exposed to air – indoor, uncontrolled (external) in SGs secondary side is also managed by the Bolting Integrity (B.2.3.9) AMP.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 009	Steel Closure bolting exposed to Air with steam or water leakage	Loss of material due to general corrosion	Chapter XI.M18, "Bolting Integrity "	No	Not used. Steel closure bolting exposed to air with steam or water leakage in the S&PC Systems is addressed by item 3.4-1, 008. As defined in Table 3.0-1, potential for leakage is considered in the air – indoor uncontrolled environment.
3.4-1, 010	Copper alloy, Nickel alloy, Steel; stainless steel, Steel; stainless steel Bolting, Closure bolting exposed to Any environment, Air – outdoor (External), Air – indoor, uncontrolled (External)	Loss of preload due to thermal effects, gasket creep, and self-loosening	Chapter XI.M18, "Bolting Integrity "	No	Consistent with NUREG-1801. Loss of preload of steel and stainless steel bolting, and closure bolting exposed to any environment, air – outdoor (external), air – indoor, uncontrolled (external) in the S&PC Systems is managed by the Bolting Integrity (B.2.3.9) AMP. Loss of preload of steel bolting exposed to air – indoor, uncontrolled (external) in the steam generators secondary side is managed by the Bolting Integrity (B.2.3.9) AMP. There are no copper alloy or nickel alloy bolting or closure bolting exposed to any environment, air – outdoor (external), or air – indoor, uncontrolled (external) in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 011	Stainless steel Piping, piping components, and piping elements, Tanks, Heat exchanger components exposed to Steam, Treated water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Cracking of stainless steel piping and piping components exposed treated water >60°C (>140°F) , including steam, in the S&PC Systems (with the exception of the Chemical Feed System) is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. Cracking of stainless steel piping and piping components exposed to treated water >60°C (>140°F) in the auxiliary Waste Processing Systems and in the S&PC Chemical Feed System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP. Cracking of stainless steel tanks exposed to treated water >60°C (>140°F) in the Main Steam System is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage cracking. There are no stainless steel heat exchanger components exposed to steam or treated water >60°C (>140°F) in the S&PC Systems.

3.4-1, 013	Steel Piping, piping components, and piping elements exposed to Treated water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Loss of material of steel piping and piping components exposed to treated water in the S&PC Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of steel piping, piping components, and heat exchanger components exposed to treated water in the CVCS is also managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 014	Steel Piping, piping components, and piping elements, PWR heat exchanger components exposed to Steam, Treated water	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Loss of material of steel piping and piping components exposed to steam and treated water in the MS System, Auxiliary Steam System, and CPS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of steel piping and piping components exposed to steam and treated water in the Containment Ventilation Systems, Primary Plant Ventilation Systems, DRMWS, EDG and Auxiliary Systems, and Chilled Water Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of steel and cast iron piping and piping components exposed to treated water in the FPS is managed by the Fire Water System (B.2.3.16) AMP, which takes exception to NUREG-1801. A generic note E and plant-specific note are used. Loss of material of steel and cast iron heat exchanger components exposed to treated water in the S&PC Systems is addressed in item 3.4-1, 015.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 015	Steel Heat exchanger components exposed to Treated water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M2, “Water Chemistry,” and Chapter XI.M32, “One-Time Inspection”	No	Consistent with exception to NUREG-1801. Loss of material of steel heat exchanger components exposed to treated water in the Main Steam and Auxiliary Steam Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of cast iron heat exchanger components exposed to treated water in the AFWS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 016	Copper alloy, Stainless steel, Nickel alloy, Aluminum Piping, piping components, and piping elements, Heat exchanger components and tubes, PWR heat exchanger components exposed to Treated water, Steam	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Loss of material of stainless steel piping, piping components, heat exchanger components and tubes exposed to treated water, including steam, in the S&PC Systems is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. Loss of material of stainless steel piping and piping components exposed to treated water, including steam, in the Chemical Feed System (specifically the pump casings and tanks) is managed by the Internal Surfaces in Miscellaneous Piping and Ducting Components AMP. A generic note E and plant-specific note are used. Loss of material of stainless steel and nickel alloy steam generator (secondary side) components; stainless steel piping, piping components, and heat exchanger components exposed to treated water in the Control Room Ventilation System, CVCS, DRMWS, EDG and Auxiliary Systems, and Process and Effluent Radiation Monitoring and Sampling System is also managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage loss of material. There are no copper alloy, nickel alloy, or aluminum piping, piping components, or heat exchanger components exposed to treated water or steam in the S&PC Systems. Furthermore, loss of material for copper alloy piping components in the FPS is managed by the Fire Water System (B.2.3.16) AMP. A generic note E and a plant-specific mote are used.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 017	Copper alloy Heat exchanger tubes exposed to Treated water	Reduction of heat transfer due to fouling	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Not applicable. There are no copper alloy heat exchanger tubes exposed to treated water in the S&PC Systems.
3.4-1, 018	Copper alloy, Stainless steel Heat exchanger tubes exposed to Treated water	Reduction of heat transfer due to fouling	Chapter XI.M2, "Water Chemistry," and Chapter XI.M32, "One-Time Inspection"	No	Consistent with exception to NUREG-1801. Reduction of heat transfer of stainless steel heat exchanger tubes exposed to treated water in the AFWS is managed by the Water Chemistry (B.2.3.2) AMP, which takes exception to NUREG-1801. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Water Chemistry (B.2.3.2) AMP to manage fouling. There are no copper alloy heat exchanger tubes exposed to treated water in the S&PC Systems.
3.4-1, 019	Stainless steel, Steel Heat exchanger components exposed to Raw water	Loss of material due to general, pitting, crevice, galvanic, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no stainless steel or steel heat exchanger components exposed to raw water in the S&PC Systems.
3.4-1, 020	Copper alloy, Stainless steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no copper alloy or stainless steel piping and piping components exposed to raw water in the S&PC Systems.

3.4-1, 021	Stainless steel Heat exchanger components exposed to Raw water	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no stainless steel heat exchanger components exposed to raw water in the S&PC Systems.
3.4-1, 022	Stainless steel, Copper alloy, Steel Heat exchanger tubes, Heat exchanger components exposed to Raw water	Reduction of heat transfer due to fouling	Chapter XI.M20, "Open-Cycle Cooling Water System"	No	Not applicable. There are no stainless steel, copper alloy, or steel heat exchanger tubes or heat exchanger components exposed to raw water in the S&PC Systems.
3.4-1, 023	Stainless steel Piping, piping components, and piping elements exposed to Closed-cycle cooling water >60°C (>140°F)	Cracking due to stress corrosion cracking	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no stainless steel piping and piping components exposed to closed-cycle cooling water >60°C (>140°F) in the S&PC Systems.
3.4-1, 024	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no steel heat exchanger components exposed to closed-cycle cooling water in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 025	Steel Heat exchanger components exposed to Closed-cycle cooling water	Loss of material due to general, pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no steel heat exchanger components exposed to closed-cycle cooling water in the S&PC Systems.
3.4-1, 026	Stainless steel Heat exchanger components, Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting and crevice corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not used. Loss of material for stainless steel heat exchanger components (channel head and shell), piping and piping components exposed to treated water in the Turbine Plant Cooling Water System are included with item 3.3-1, 049. There are no other stainless steel heat exchanger components, piping, and piping components exposed to closed-cycle cooling water in the S&PC Systems.
3.4-1, 027	Copper alloy Piping, piping components, and piping elements exposed to Closed-cycle cooling water	Loss of material due to pitting, crevice, and galvanic corrosion	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no copper alloy piping and piping components exposed to closed-cycle cooling water in the S&PC Systems.
3.4-1, 028	Steel, Stainless steel, Copper alloy Heat exchanger components and tubes, Heat exchanger tubes exposed to Closed-cycle cooling water	Reduction of heat transfer due to fouling	Chapter XI.M21A, "Closed Treated Water Systems"	No	Not applicable. There are no steel, stainless steel, or copper alloy heat exchanger tubes exposed to closed-cycle cooling water in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 029	Steel Tanks exposed to Air – outdoor (External)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel tanks exposed to air – outdoor (external) in the S&PC Systems.
3.4-1, 030	Steel, Stainless Steel, Aluminum Tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to Soil or Concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to general (steel only), pitting, and crevice corrosion; cracking due to stress corrosion cracking (stainless steel and aluminum only)	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel, stainless steel, or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to soil, air-indoor uncontrolled, moist air, or condensation external environments in the S&PC Systems. The stainless steel liner of the concrete CST is exposed to outdoor air, above the waterline from tank vents, and to concrete and addressed in items 3.4-1, 003 and 3.4-1, 058, respectively.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems					
Item	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4-1, 031	Stainless steel, Aluminum Tanks (within the scope of Chapter XI.M29, “Aboveground Metallic Tanks”) exposed to Soil or Concrete, or the following external environments air-outdoor, air-indoor uncontrolled, moist air, condensation	Loss of material due to pitting, and crevice corrosion; cracking due to stress corrosion cracking	Chapter XI.M29, “Aboveground Metallic Tanks”	No	Not applicable. There are no stainless steel or aluminum tanks (within the scope of Chapter XI.M29, “Aboveground Metallic Tanks”) exposed to soil or concrete, or to air-outdoor, air-indoor uncontrolled, moist air, or condensation environments in the S&PC Systems, as clarified for item 3.4-1, 030.
3.4-1, 032	Gray cast iron Piping, piping components, and piping elements exposed to Soil	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Not applicable. There are no gray cast iron piping and piping components exposed to soil in the S&PC Systems.
3.4-1, 033	Gray cast iron, Copper alloy (>15% Zn or >8% Al) Piping, piping components, and piping elements exposed to Treated water, Raw water, Closed-cycle cooling water	Loss of material due to selective leaching	Chapter XI.M33, “Selective Leaching”	No	Consistent with NUREG-1801. Selective leaching of cast iron piping components exposed to treated water in the AFWS and Auxiliary Steam System is managed by the Selective Leaching (B.2.3.20) AMP. There are no copper alloy (>15% Zn or >8% Al) piping and piping components exposed to treated water, raw water, or closed-cycle cooling water in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems					
Item	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4-1, 034	Steel External surfaces exposed to Air – indoor, uncontrolled (External), Air – outdoor (External), Condensation (External)	Loss of material due to general corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Consistent with NUREG-1801. Loss of material of steel external surfaces exposed to air – indoor, uncontrolled (external) or air – outdoor (external) in the S&PC Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP.
3.4-1, 035	Aluminum Piping, piping components, and piping elements exposed to Air - outdoor	Loss of material due to pitting and crevice corrosion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no aluminum piping and piping components exposed to air (outdoor) in the S&PC Systems.
3.4-1, 036	Steel Piping, piping components, and piping elements exposed to Air – outdoor (Internal)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material of steel piping and piping components exposed to air – outdoor (internal) in the Main Steam System, as well as the Control Room Ventilation, Miscellaneous Ventilation, and EDG and Auxiliary Systems is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.4-1, 037	Steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no steel piping and piping components exposed to condensation (internal) in the S&PC System.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 038	Steel Piping, piping components, and piping elements exposed to Raw water	Loss of material due to general, pitting, crevice, galvanic, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Consistent with NUREG-1801. Loss of material and fouling of steel piping and piping components exposed to raw water in the Condenser Vacuum System is managed by the Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP.
3.4-1, 039	Stainless steel Piping, piping components, and piping elements exposed to Condensation (Internal)	Loss of material due to pitting and crevice corrosion	Chapter XI.M38, "Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components"	No	Not applicable. There are no stainless steel piping and piping components exposed to condensation (internal) in the S&PC Systems.
3.4-1, 040	Steel Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of steel piping and piping components exposed to lubricating oil in the Turbine-Driven Auxiliary Feedwater Pump Lubricating Oil System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.
3.4-1, 041	Steel Heat exchanger components exposed to Lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of steel heat exchanger components exposed to lubricating oil in the Turbine-Driven Auxiliary Feedwater Pump Lubricating Oil System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 042	Aluminum Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no aluminum piping and piping components exposed to lubricating oil in the S&PC Systems.
3.4-1, 043	Copper alloy Piping, piping components, and piping elements exposed to Lubricating oil	Loss of material due to pitting and crevice corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no copper alloy piping and piping components exposed to lubricating oil in the S&PC Systems.
3.4-1, 044	Stainless steel Piping, piping components, and piping elements, Heat exchanger components exposed to Lubricating oil	Loss of material due to pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Loss of material of stainless steel heat exchanger components exposed to lubricating oil in the Turbine-Driven Auxiliary Feedwater Pump Lubricating Oil System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage loss of material. There are no stainless steel piping and piping components exposed to lubricating oil in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems					
Item	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4-1, 045	Aluminum Heat exchanger components and tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Not applicable. There are no aluminum heat exchanger components and tubes exposed to lubricating oil in the S&PC Systems.
3.4-1, 046	Stainless steel, Steel, Copper alloy Heat exchanger tubes exposed to Lubricating oil	Reduction of heat transfer due to fouling	Chapter XI.M39, "Lubricating Oil Analysis," and Chapter XI.M32, “One-Time Inspection”	No	Consistent with NUREG-1801. Reduction of heat transfer of stainless steel heat exchanger tubes exposed to lubricating oil in the Turbine-Driven Auxiliary Feedwater Pump Lubricating Oil System is managed by the Lubricating Oil Analysis (B.2.3.25) AMP. The One-Time Inspection (B.2.3.19) AMP will verify the effectiveness of the Lubricating Oil Analysis (B.2.3.25) AMP to manage fouling. There are no steel or copper alloy heat exchanger tubes exposed to lubricating oil in the S&PC Systems.
3.4-1, 047	Steel (with coating or wrapping), stainless steel, nickel-alloy piping, piping components, and piping elements; tanks exposed to Soil or Concrete	Loss of material due to general (steel only), pitting, crevice, and microbiologically-influenced corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no buried or underground steel (with coating or wrapping), stainless steel, nickel-alloy piping, piping components, or tanks exposed to soil or concrete in the S&PC Systems.
3.4-1, 048	Stainless steel, nickel alloy bolting exposed to soil	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no stainless steel or nickel alloy bolting exposed to soil in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 049	Stainless steel, nickel alloy piping, piping components, and piping elements exposed to soil or concrete	Loss of material due to pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no stainless steel or nickel alloy piping and piping components exposed to soil or concrete in the S&PC Systems.
3.4-1, 050	Steel Bolting exposed to Soil	Loss of material due to general, pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There is no steel bolting exposed to soil in the S&PC Systems.
3.4-1, 050.5	Underground stainless steel, nickel alloy, steel piping, piping components, and piping elements	Loss of material due to general (steel only), pitting and crevice corrosion	Chapter XI.M41, "Buried and Underground Piping and Tanks"	No	Not applicable. There are no underground stainless steel, nickel alloy, or steel piping and piping components in the S&PC Systems. Some of the piping and piping components to/from the stainless steel-lined concrete CST in the AFWS are located below-grade in the tunnel that is considered an extension of (room in) the SGBs and, therefore, exposed to indoor air and included with items 3.4-1, 034 and 3.4-1, 058 for steel and stainless steel, respectively.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 051	Steel Piping, piping components, and piping elements exposed to Concrete	None	None, provided attributes of the concrete are consistent with ACI 318 or ACI 349 (low water-to-cement ratio, low permeability, and adequate air entrainment) as cited in NUREG-1557, and plant OE indicates no degradation of the concrete	No, if conditions are met.	Not applicable. There are no steel piping and piping components exposed to concrete in the S&PC Systems.
3.4-1, 052	Aluminum Piping, piping components, and piping elements exposed to Gas, Air – indoor, uncontrolled (Internal/External)	None	None	NA - No AEM or AMP	Not applicable. There are no aluminum piping and piping components exposed to gas or air – indoor, uncontrolled (internal/external) in the S&PC Systems.
3.4-1, 053	Copper alloy (≤15% Zn and ≤8% Al) Piping, piping components, and piping elements exposed to Air with borated water leakage	None	None	NA - No AEM or AMP	Not applicable. There are no copper alloy (≤15% Zn and ≤8% Al) piping and piping components exposed to air with borated water leakage in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 054	Copper alloy Piping, piping components, and piping elements exposed to Gas, Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no copper alloy piping and piping components exposed to gas or air – indoor, uncontrolled (external) in the S&PC Systems.
3.4-1, 055	Glass Piping elements exposed to Lubricating oil, Air – outdoor, Condensation (Internal/External), Raw water, Treated water, Air with borated water leakage, Gas, Closed-cycle cooling water, Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no glass piping elements exposed to lubricating oil, air – outdoor, condensation (internal/external), raw water, treated water, air with borated water leakage, gas, closed-cycle cooling water, or air – indoor, uncontrolled (external) in the S&PC Systems.
3.4-1, 056	Nickel alloy Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External)	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy piping and piping components exposed to air – indoor, uncontrolled (external) in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems					
Item	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4-1, 057	Nickel alloy, PVC Piping, piping components, and piping elements exposed to Air with borated water leakage, Air – indoor, uncontrolled, Condensation (Internal)	None	None	NA - No AEM or AMP	Not applicable. There are no nickel alloy, PVC piping, or piping components exposed to air with borated water leakage, air – indoor, uncontrolled, condensation (internal) in the S&PC Systems.
3.4-1, 058	Stainless steel Piping, piping components, and piping elements exposed to Air – indoor, uncontrolled (External), Concrete, Gas, Air – indoor, uncontrolled (Internal)	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.
3.4-1, 059	Steel Piping, piping components, and piping elements exposed to Air – indoor controlled (External), Gas	None	None	NA - No AEM or AMP	Consistent with NUREG-1801.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 060	Any material, piping, piping components, and piping elements exposed to treated water	Wall thinning due to erosion	Chapter XI.M17, "Flow-Accelerated Corrosion"	No	Consistent with exception to NUREG-1801 as supplemented by LR-ISG-2012-01. Wall thinning of susceptible carbon steel and stainless steel piping and piping components exposed to treated water in the S&PC Systems is managed by the Flow-Accelerated Corrosion (B.2.3.8) AMP, which takes exception to NUREG-1801.
3.4-1, 061	Metallic piping, piping components, and tanks exposed to raw water or waste water	Loss of material due to recurring internal corrosion	A plant-specific aging management program is to be evaluated to address recurring internal corrosion	Yes, plant-specific (See subsection 3.4.2.2.6)	Not applicable. S&PC components containing raw water or waste water have not evidenced recurring internal corrosion. However, LR-ISG-2012-02 Appendix H clarifies the applicability of recurring internal corrosion to water environments other than raw water or waste water, if revealed by plant-specific OE. As such, loss of material due to recurring internal corrosion in carbon steel TPCW piping exposed to closed-cycle cooling water is managed by the Closed Treated Water Systems (B.2.3.12) AMP, which takes exception to NUREG-1801. A generic note H and a plant-specific note are used in Table 3.4.2-4f. Further evaluation is documented in subsection 3.4.2.2.6.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems					
Item	**Component**	**Aging Effect/Mechanism**	**Aging Management Programs**	**Further Evaluation Recommended**	**Discussion**
3.4-1, 062	Steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to treated water	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M29, "Aboveground Metallic Tanks"	No	Not applicable. There are no steel, stainless steel or aluminum tanks (within the scope of Chapter XI.M29, "Aboveground Metallic Tanks") exposed to treated water in the S&PC Systems. Loss of material for the stainless steel liner of the concrete CST exposed to treated water, in the AFWS, is addressed in item 3.4-1, 012. Other than the stainless steel-lined concrete CST, tanks in the S&PC Systems are located indoors with volumes less than 100,000 gallons and do not meet the scope of XI.M29 as supplemented by LR-ISG-2012-02.
3.4-1, 063	Insulated steel, stainless steel, copper alloy, aluminum, or copper alloy (> 15% Zn) piping, piping components, and tanks exposed to condensation, air-outdoor	Loss of material due to general (steel, and copper alloy), pitting, or crevice corrosion, and cracking due to stress corrosion cracking (aluminum, stainless steel and copper alloy (>15% Zn) only)	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components" or Chapter XI.M29, "Aboveground Metallic Tanks" (for tanks only)	No	Consistent with NUREG-1801 as supplemented by LR-ISG-2012-02. Loss of material of steel and stainless steel piping, and piping components exposed to outdoor air in the Feedwater and Main Steam Systems is managed by the External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP. There are no insulated copper alloy, aluminum, or copper alloy (> 15% Zn) piping, and piping components in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 064	Jacketed calcium silicate or fiberglass insulation in an air-indoor uncontrolled or air-outdoor environment	Reduced thermal insulation resistance due to moisture intrusion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not used. The only credited insulation function associated with S&PC Systems is the insulation integral to the “hot pipe” Containment penetrations, addressed in Table 3.5.2-1. The External Surfaces Monitoring of Mechanical Components (B.2.3.22) AMP will be used to manage aging effect of reduced thermal insulation resistance (IR) for jacketed calcium silicate or fiberglass insulation in ESF areas of the Safeguards Buildings and AB, as listed in Table 3.5.2-13.
3.4-1, 065	Jacketed foamglas ® (glass dust) insulation in an air-indoor uncontrolled or air-outdoor environment	Reduced thermal insulation resistance due to moisture intrusion	Chapter XI.M36, "External Surfaces Monitoring of Mechanical Components"	No	Not applicable. There are no jacketed Foamglas ® (glass dust) insulation in an air-indoor uncontrolled or air-outdoor environment in the S&PC Systems.
3.4-1, 066	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of coating or lining integrity due to blistering, cracking, flaking, peeling, delamination, rusting, or physical damage, and spalling for cementitious coatings/linings	Chapter XI.M42, “Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks”	No	Not applicable. There are no metallic heat exchangers, or tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil in the S&PC Systems.

Table 3.4-1: Summary of Aging Management Programs for Steam and Power Conversion Systems

Item	Component	Aging Effect/Mechanism	Aging Management Programs	Further Evaluation Recommended	Discussion
3.4-1, 067	Metallic piping, piping components, heat exchangers, tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil	Loss of material due to general, pitting, crevice, and microbiologically-influenced corrosion; fouling that leads to corrosion	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. As described in item 3.4-1, 066, there are no metallic heat exchangers, or tanks with internal coatings/linings exposed to closed-cycle cooling water, raw water, treated water, treated borated water, or lubricating oil in the S&PC Systems.
3.4-1, 068	Gray cast iron piping components with internal coatings/linings exposed to closed-cycle cooling water, raw water, or treated water	Loss of material due to selective leaching	Chapter XI.M42, "Internal Coatings/Linings for In-Scope Piping, Piping Components, Heat Exchangers, and Tanks"	No	Not applicable. There are no cast iron components with internal linings/coatings in the S&PC Systems.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

I. Aging effect in NUREG-1801 for this component, material and environment combination is not applicable.

Plant-Specific Notes

1. The external concrete portion of the CST is evaluated with the Yard structures in Table 3.5.2-10.

2. Aging effects not applicable, for more information see Sections 3.4.2.2.2 and 3.4.2.2.3.

3. Structural support functions of moment restraints are managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP and evaluated in Table 3.5.2-13.

4. Compressed (dry) air is supplied to the air accumulators and attached components from the Instrument Air System for air-operated AFW control valves.

5. Conservatively, the liner and makeup/vent lines inside the CST are exposed to outdoor air above the waterline where contaminants could concentrate.

Generic Notes

A. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP is consistent with NUREG-1801 AMP description.

B. Consistent with component, material, environment, aging effect, and AMP listed for NUREG-1801 line item. AMP has exceptions to NUREG-1801 AMP description.

C. Component is different, but consistent with NUREG-1801 for material, environment, aging effect, and AMP. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

1) Structural support functions of moment restraints are managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP and evaluated in Table 3.5.2-13.

2) Only components within the Feedwater System are subject to cumulative fatigue damage; components within the Condensate System are not exposed to high temperatures.

3) The CASS flow elements are housed entirely inside a carbon steel spool piece, which provides the leakage boundary for the component.

4) Consistent with OE contained in NUREG-2191, Item VII.E1.A-57, Table 3.3-1, 002 is used to manage cumulative fatigue damage of stainless steel piping components exposed to any environment.

5) Feedwater piping has an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

Plant-Specific Notes

1. The SG blowdown heat exchanger contains the same treated condensate water, at different temperatures, on both the shell and tube sides (i.e., incoming blowdown on the tube side and returning blowdown on the shell side); as such, the internal environment for both the heat exchanger shell and channel head is listed as treated water.

2. Structural support functions of moment restraints are managed by the ASME Section XI, Subsection IWF (B.2.3.31) AMP and evaluated in Table 3.5.2-13.

3. Piping associated with the following components have an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4: MS line – piping upstream of MSIVs, main steam line – piping downstream of MSIVs, MS line – admitted for operation of the turbine drive auxiliary feedwater pump, steam generator blowdown and heater drains.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

Plant-Specific Notes

1. Auxiliary Steam piping has an existing fatigue analysis as described in Section 4.3.3 and Table 4.3.1-4.

Table 3.4.2-4b: Chemical Feed and Hydrazine Injection – Summary of Aging Management Evaluation								
Component Type	**Intended Function**	**Material**	**Environment**	**Aging Effect Requiring Management**	**Aging Management Program**	**NUREG-1801 Item**	**Table 1 Item**	**Notes**

Valve body	Structural integrity (attached)	Stainless steel	Air - indoor uncontrolled (internal)	None	None	VIII.I.SP-86	3.4-1, 058	A

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. The Inspection of Internal Surfaces in Miscellaneous Piping and Ducting Components (B.2.3.24) AMP is used to manage the aging effects for this component, material, and environment combination.

Table 3.4.2-4c: Condensate Polishing System – Summary of Aging Management Evaluation

Component Type	Intended Function	Material	Environment	Aging Effect Requiring Management	Aging Management Program	NUREG-1801 Item	Table 1 Item	Notes

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

H. Aging effect not in NUREG-1801 for this component, material, and environment combination.

Plant-Specific Notes

1. Portions of the Turbine Plant Cooling Water System within the AB are susceptible to air with borated water leakage.
2. LR-ISG-2012-02, Appendix H recommends a review of OE for RIC in the Closed Treated Water System AMP. This review was performed, and it identified that RIC exists in the Turbine Plant Cooling Water System. The enhanced Closed Treated Water Systems (B.2.3.12) AMP will be used to address inspection recommended by LR-ISG-2012-02.

3.5. AGING MANAGEMENT OF CONTAINMENTS, STRUCTURES, AND COMPONENT SUPPORTS

3.5.1. Introduction

This section provides the results of the AMR for those components identified in Section 2.4, “Scoping and Screening Results: Structures”. The systems, or portions of systems, which are addressed in this section are described in the indicated sections.

- Containment Buildings (2.4.1)
- Auxiliary Building (2.4.2)
- Diesel Generator Buildings (2.4.3)
- Electrical and Control Building (2.4.4)
- Fuel Building (2.4.5)
- Safeguards Buildings (2.4.6)
- Safe Shutdown Impoundment and Dam (2.4.7)
- Service Water Intake Structure (2.4.8)
- Switchgear Buildings (2.4.9)
- Turbine Buildings (2.4.10)
- Yard Structures (2.4.11)
- Switchyard Structures (2.4.12)

- Crane/Hoist Commodity Group (2.4.14)
- Fire Barrier Commodity Group (2.4.15)

3.5.2. Results

The following tables summarize the results of the AMR for Containments, Structures, and Component Supports.

Table 3.5.2-1: Containment Buildings - Summary of Aging Management Evaluation

Table 3.5.2-2: Auxiliary Building - Summary of Aging Management Evaluation

Table 3.5.2-3: Diesel Generator Buildings - Summary of Aging Management Evaluation

Table 3.5.2-4: Electrical and Control Building - Summary of Aging Management Evaluation

Table 3.5.2-5: Fuel Building - Summary of Aging Management Evaluation

Table 3.5.2-6: Safeguards Buildings - Summary of Aging Management Evaluation

Table 3.5.2-7: Safe Shutdown Impoundment and Dam - Summary of Aging Management Evaluation

3.5.2.1. Materials, Environments, Aging Effects Requiring Management and Aging Management Programs

3.5.2.1.1. Containment Buildings

Materials

The materials of construction for the RCB components are:

- Calcium silicate
- Coatings
- Concrete (reinforced)
- Dissimilar metal welds
- Elastomer
- Grout (Unit 2 RV support reorientation)
- Lubrite®
- RTV foam
- Stainless steel
- Steel (carbon steel)

Environments

The in-scope RCB components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage

- Concrete
- Groundwater/soil (reactor vessel cavity pit)
- Soil
- Treated borated water
- Water-flowing (rainwater, groundwater)

Aging Effects Requiring Management

The following aging effects associated with the RCB structural components require management:

- Cracking
- Cumulative fatigue damage
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of coating or lining integrity
- Loss of leak tightness
- Loss of material
- Loss of mechanical function
- Loss of preload
- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the RCB structural components:

- 10 CFR Part 50, Appendix J (B.2.3.32)
- ASME Section XI, Subsection IWE (B.2.3.29)
- ASME Section XI, Subsection IWF (B.2.3.31)
- ASME Section XI, Subsection IWL (B.2.3.30)
- Boric Acid Corrosion (B.2.3.4)
- One-Time Inspection (B.2.3.19)
- Protective Coating Monitoring and Maintenance (B.2.3.36)
- Structures Monitoring (B.2.3.34)
- TLAA (Section 4.6)
- Water Chemistry (B.2.3.2)

3.5.2.1.2. Auxiliary Building

Materials

The materials of construction for the AB structural components are:

- Carbon steel
- Concrete (reinforced)
- Elastomer
- Galvanized steel
- Grout
- Masonry block

Environments

The AB structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Groundwater/soil (perched water)
- Soil
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the AB structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the AB structural components:

- Boric Acid Corrosion (B.2.3.4)
- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.3. Diesel Generator Buildings

Materials

The materials of construction for the DGBs structural components are:

- Carbon steel
- Concrete (reinforced)
- Elastomer
- Galvanized steel
- Grout
- Masonry block
- Stainless steel

Environments

The DGBs structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/soil (perched water)
- Soil
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the DGBs structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of sealing

- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the DGBs structural components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.4. Electrical and Control Building

Materials

The materials of construction for the ECB structural components are:

- Carbon steel
- Concrete (reinforced)
- Elastomer
- Galvanized steel
- Grout
- Masonry block
- Stainless steel

Environments

The ECB structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/Soil
- Soil
- Water-flowing (heavy rains, groundwater below water table)

Aging Effects Requiring Management

The following aging effects associated with the ECB structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload

- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the ECB structural components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.5. Fuel Building

Materials

The materials of construction for the FB structural components are:

- Boral
- Carbon steel
- Concrete (reinforced)
- Elastomer
- Grout
- Masonry block
- Stainless steel

Environments

The FB structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Groundwater/soil (perched water)
- Soil
- Treated borated water
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the FB structural components require management:

- Changes in dimensions
- Cracking
- Distortion

- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity
- Reduction of neutron-absorbing capacity

Aging Management Programs

The following AMPs manage the aging effects for the FB structural components:

- Boric Acid Corrosion (B.2.3.4)
- Masonry Walls (B.2.3.33)
- Monitoring of Neutron-Absorbing Materials Other than Boraflex (B.2.3.26)
- One-Time Inspection (B.2.3.19)
- Structures Monitoring (B.2.3.34)
- Water Chemistry (B.2.3.2)

In addition, monitoring of the spent fuel water level in accordance with technical specifications (TSs) (Amendment 176) and monitoring of leakage from the leak chase channels performed as part of the Structures Monitoring (B.2.3.34) AMP verifies the effectiveness of the SFP water chemistry.

3.5.2.1.6. Safeguards Buildings

Materials

The materials of construction for the SGBs structural components are:

- Carbon steel
- Concrete (reinforced)
- Elastomer
- Galvanized steel
- Grout
- Masonry block
- Stainless steel

Environments

The SGBs structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Groundwater/Soil
- Soil
- Water-flowing (heavy rains, groundwater below water table)

Aging Effects Requiring Management

The following aging effects associated with the SGBs structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the SGBs structural components:

- Boric Acid Corrosion (B.2.3.4)
- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.7. Safe Shutdown Impoundment and Dam

Materials

The materials of construction for the SSI and Dam are:

- Earth
- Rip rap (rock-fill)

Environments

The SSI and Dam are exposed to the following environments:

- Air – outdoor
- Water – flowing or standing

Aging Effects Requiring Management

The following aging effects associated with the SSI and Dam require management:

- Loss of material
- Loss of form

Aging Management Programs

The following AMP manages the aging effects for the SSI and Dam components:

- RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35)

3.5.2.1.8. Service Water Intake Structure

Materials

The materials of construction for the SWIS and structural components are:

- Carbon steel
- Concrete (reinforced)
- Grout
- Masonry block

Environments

The SWIS and structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/Soil
- Soil
- Water - flowing

Aging Effects Requiring Management

The following aging effects associated with the SWIS, and structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the SWIS and structural components:

- Masonry Walls (B.2.3.33)
- RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35)
- Structures Monitoring (B.2.3.34)

3.5.2.1.9. Switchgear Buildings

Materials

The materials of construction for the Switchgear buildings and structural components are:

- Carbon steel
- Concrete (reinforced)
- Galvanized steel
- Grout
- Masonry block

Environments

The Switchgear buildings and structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/soil (perched water)

- Soil
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the Switchgear buildings and structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the Switchgear buildings and structural components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.10. Turbine Buildings

Materials

The materials of construction for the TBs and structural components are:

- Carbon steel
- Concrete (reinforced)
- Grout
- Masonry block

Environments

The TBs and structural components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/Soil
- Soil
- Water-flowing (heavy rains, groundwater below the water table)

Aging Effects Requiring Management

The following aging effects associated with the TBs and structural components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the TBs and structural components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.11. Yard Structures

Materials

The materials of construction for the Yard Structures and components are:

- Carbon steel
- Concrete (reinforced)
- Elastomer
- Galvanized steel
- Grout
- Masonry block

Environments

The Yard Structures and components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/soil (perched water)
- Soil
- Stainless steel
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the Yard Structures and components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of sealing
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the Yard Structures and components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.12. Switchyard Structures

Materials

The materials of construction for the Switchyard Structures are:

- Carbon steel
- Concrete (reinforced)
- Galvanized steel
- Grout
- Masonry block

Environments

The in-scope Switchyard Structures and components are exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Groundwater/soil (perched water)
- Soil
- Water-flowing (heavy rains)

Aging Effects Requiring Management

The following aging effects associated with the Switchyard Structures and components require management:

- Cracking
- Distortion
- Increase in porosity and permeability
- Loss of bond
- Loss of material
- Loss of preload
- Loss of strength
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the Switchyard Structures and components:

- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.1.13. Component Support Commodity Group

Materials

The materials of construction for the Component Support Commodity Group are:

- Aluminum
- Calcium silicate
- Carbon steel
- Ceramic fiber
- Concrete (reinforced)
- Copper alloy > 15% Zn or > 8% Al
- Elastomer
- Fiberglass
- Galvanized steel
- Grout
- Silicone foam
- Stainless steel

Environments

The Component Support Commodity Group is exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage
- Raw water
- Treated borated water

Aging Effects Requiring Management

The following aging effects associated with the Component Support Commodity Group require management:

- Change in material properties
- Cracking
- Loss of bond
- Loss of material
- Loss of mechanical function
- Loss of preload
- Loss of sealing
- Reduction in concrete anchor capacity

Aging Management Programs

The following AMPs manage the aging effects for the Component Support Commodity Group:

- ASME Section XI, Subsection IWF (B.2.3.31)
- Boric Acid Corrosion (B.2.3.4)
- External Surfaces Monitoring of Mechanical Components (B.2.3.22)
- Selective Leaching (B.2.3.20)
- Structures Monitoring (B.2.3.34)
- Water Chemistry (B.2.3.2)

3.5.2.1.14. Crane/Hoist Commodity Group

Materials

The materials of construction for the Crane/Hoist Commodity Group are:

- Carbon steel

Environments

The Crane/Hoist Commodity Group is exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage

Aging Effects Requiring Management

The following aging effects associated with the Crane/Hoist Commodity Group require management:

- Cumulative fatigue damage
- Loss of material
- Loss of preload

Aging Management Programs

The following AMPs manage the aging effects for the Crane/Hoist Commodity Group:

- Boric Acid Corrosion (B.2.3.4)
- Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.3.13)
- Structures Monitoring (B.2.3.34)
- TLAA (Section 4.7.4)

3.5.2.1.15. Fire Barrier Commodity Group

Materials

The materials of construction for the Fire Barrier Commodity Group are as follows:

- Aluminum
- Carbon steel
- Ceramic fiber/blanket
- Concrete
- Concrete (reinforced)

- Elastomer
- Galvanized steel
- Gypsum
- Masonry block
- Silicate radiant energy shield (Kaowool, Cerafiber, Cera blanket, Siltemp WR 84 CSR, Avsil 84CSR fabric and similar)
- Stainless steel
- Subliming compound (Thermo-lag, Carboline and similar)

Environments

The Fire Barrier Commodity Group is exposed to the following environments:

- Air – indoor uncontrolled
- Air – outdoor
- Air with borated water leakage

Aging Effects Requiring Management

The following aging effects associated with Fire Barrier Commodity Group require management:

- Change in material properties
- Cracking
- Delamination
- Hardening
- Loss of bond
- Loss of material
- Loss of strength
- Separation
- Shrinkage

Aging Management Programs

The following AMPs manage the aging effects for the Fire Barrier Commodity Group:

- Boric Acid Corrosion (B.2.3.4)
- Fire Protection (B.2.3.15)
- Masonry Walls (B.2.3.33)
- Structures Monitoring (B.2.3.34)

3.5.2.2. AMR Results for Which Further Evaluation is Recommended by the GALL Report

3.5.2.2.1. Containments

For the RCB, the following sections provide the CPNPP disposition to those areas requiring FE.

3.5.2.2.1.1. Cracking and Distortion due to Increased Stress Levels from Settlement; Reduction of Foundation Strength, and Cracking due to Differential Settlement and Erosion of Porous Concrete Subfoundations

Cracking and distortion due to increased stress levels from settlement could occur in PWR and BWR concrete and steel containments. The existing program relies on ASME Section XI, Subsection IWL to manage these aging effects. Also, reduction of foundation strength and cracking, due to differential settlement and erosion of porous concrete subfoundations could occur in all types of PWR and BWR containments. The existing program relies on the structures monitoring program to manage these aging effects. However, some plants may rely on a dewatering system to lower the site ground water level. If the plant's current licensing basis (CLB) credits a de-watering system to control settlement, the GALL Report recommends further evaluation to verify the continued functionality of the de-watering system during the period of extended operation.

As described in Section 2.4.1, the CPNPP RCB consists of a vertical cylinder and a hemispherical dome; supported on an essentially flat foundation mat with a reactor cavity pit projection. The foundation mat is 12-ft of reinforced concrete, for which the top sits approximately 4-ft 6-in below grade. The foundation consists of firm, unweathered Glen Rose Limestone with no liquefaction susceptible soils present, which constitutes the principal bedrock formation. No structural backfill is used under or against the RCB.

No groundwater was encountered during excavation and construction of the plant structures. Also, there is no dewatering at the site during or after construction. No groundwater was encountered in the primary Glen Rose Limestone, and therefore only normal pumping equipment and procedures were required to remove storm runoff and concrete curing water which collected in the open excavations. The maximum predicted settlement is 0.26-in at the center of the reactor containment. Since the settlement is elastic, it is expected to occur immediately after the final load application. There has been no plant-specific OE indicating notable cracking or distortion due to settlement. As such, reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation is not an applicable aging effect for the CPNPP RCB. Furthermore, differential settlement is not expected to occur. However, consistent with NUREG-1801, the Structures Monitoring (B.2.3.34) AMP, which informs the ASME Section XI, Subsection IWL (B.2.3.30) AMP, will be used to manage potential settlement cracking and distortion for RCB concrete during the PEO.

3.5.2.2.1.2. Reduction of Strength and Modulus due to Elevated Temperature

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR concrete and steel containments. The implementation of 10 CFR 50.55a and ASME Section XI, Subsection IWL would not be able to identify the reduction of strength and modulus of concrete due to elevated temperature. Subsection CC-3440 of ASME Section III, Division 2, specifies the concrete temperature limits for normal operation or any other long-term period. The GALL Report recommends further evaluation of a plant-specific aging management program if any portion of the concrete containment components exceeds specified temperature limits, i.e., general area temperature greater than 66°C (150°F) and local area temperature greater than 93°C (200°F). Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

The average internal temperature of the CPNPP RCB is limited to 120ºF during normal plant operation. General area temperatures inside RCB will not result in concrete temperatures in excess of 150ºF. However, local area temperatures may be elevated above general area temperatures due to process piping carrying high temperature fluids (e.g., MS, and feedwater piping RCB penetrations and RCL cold and hot leg piping through the biological shield tunnel in the primary shield wall).

Stainless steel reflective (mirror) type thermal insulation is placed between “hot pipe” process pipe and carbon steel RCB penetration sleeves. In addition, multiple pipe penetrations include calcium silicate insulation encased in the penetration assembly around the process pipe anchor sleeves. The AFWS is used in Mode 2 and 3 to maintain the SG water levels. During plant startup a switch over of feedwater supply from AFW to the main Feedwater System is made via a preheater bypass line for Unit 2 only. Prior to this switch, main feedwater is preheated, and the switch is made at approximately 15 percent power, at which time feedwater temperatures are above 250ºF. To comply with the requirements of ASME Section III, Division 2, paragraph CC-3430 on concrete temperatures, the unit 2 “cold” penetrations (MV-17, MV-18, MV-19, and MV-20) along the preheater bypass flow path, are subject to an administrative time limit of 24 hours for operating temperatures above 250ºF. The preheater bypass line for Unit 1 has been removed; as such the Unit 1 feedwater bypass penetrations (MV-17, 18, 19, 20) are only subject to the maximum AFW temperature of 122ºF.

Within the RCB, concrete pipe tunnels connect the SG subcompartments to the reactor vessel cavity. The non-safety related reactor coolant pipe penetration cooling in PSW System is designed to dissipate heat conducted to the piping supports by the reactor coolant lines utilizing forced convection to prevent dehydration of concrete during normal operation only. In addition, reflective insulation assemblies are installed on the RCS cold leg and hot leg pipes located inside these biological shield tunnels.

A review of the CPNPP RCB OE has not revealed any reports of localized concrete temperatures exceeding 200ºF. In addition, the RCB penetration and reactor coolant piping insulation contributes to keeping the local concrete temperatures of the RCB and PSW below 200ºF during normal plant operation. As such, this insulation has a LR intended function as described in Table 2.4-1 and is subject to AMR as listed in Table 3.5.2-1. Therefore, reduction of strength and modulus due to elevated temperatures do not require management for RCB concrete during the PEO.

3.5.2.2.1.3. Loss of Material due to General, Pitting and Crevice Corrosion

1. *Loss of material due to general, pitting, and crevice corrosion could occur in steel elements of inaccessible areas for all types of PWR and BWR containments. The existing program relies on ASME Section XI, Subsection IWE, and 10 CFR Part 50, Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of plant-specific programs to manage this aging effect if corrosion is indicated from the IWE examinations. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

ASME Section XI, Subsection IWE (B.2.3.29) and 10 CFR Part 50, Appendix J (B.2.3.32) AMP will be used to manage the loss of material of steel elements of Containment, with inspection of accessible areas the leading indicator for inaccessible areas.

OE with inspection of the accessible areas of the containment liner and moisture barrier is summarized in the ASME Section XI, Subsection IWE (B.2.3.29) AMP. In addition, the 10 CFR Part 50, Appendix J (B.2.3.32) AMP inspections include a general visual examination of the Containment during each outage.

Furthermore, during each Containment ISI (CISI) interval, surface areas likely to experience accelerated degradation and aging require augmented examination. Areas previously identified by the CPNPP Coatings Program as "areas/items of specific interest" are also considered to require special attention for CISI examination. An evaluation of the acceptability of inaccessible areas is required when conditions exist in augmented areas that could indicate degradation could also exist or could have extended into the inaccessible areas. Such augmented inspections are either visual (VT-1) or ultrasonic as warranted by the findings during that interval. A review of plant OE and IWE inspection reports has not identified instances of liner corrosion beyond minor surface corrosion that was evaluated and corrected and has not identified any degradation that originated on the inaccessible side of the liner.

Additionally, a Containment alternate access opening in Unit 1 was created and restored to provide access for the SG and reactor vessel head replacement in 2007. The creation and restoration of the access opening required a section of the Containment liner plate to be cut out and then rewelded with a full penetration weld. Post-modification and subsequent inspections of the restored section of the Unit 1 Containment liner did not identify any corrosion or bulging of the liner (as could be expected if water got between the liner and Containment concrete).

As such, for CPNPP no additional plant-specific activities are warranted beyond those described above and those that are currently established for inaccessible areas of the Containment liner.

2. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus shell of Mark I containments. The existing program relies on ASME Section XI, Subsection IWE, and 10 CFR Part 50, Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of plant-specific programs to manage this aging effect if corrosion is significant. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

The CPNPP RCB is a Seismic Category I, fully continuous, steel-lined, reinforced concrete structure which consists of a vertical cylinder with a hemispherical dome supported on a foundation mat with a reactor cavity pit projection. CPNPP is a PWR, which does not have a steel torus shell. Therefore, this item does not apply to CPNPP.

3. *Loss of material due to general, pitting, and crevice corrosion could occur in steel torus ring girders and downcomers of Mark I containments, downcomers of Mark II containments, and interior surface of suppression chamber shell of Mark III containments. The existing program relies on ASME Section XI, Subsection IWE to manage this aging effect. The GALL Report recommends further evaluation of plant-specific programs to manage this aging effect if corrosion is significant. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR)*

The CPNPP RCB is a Seismic Category I, fully continuous, steel-lined, reinforced concrete structure which consists of a vertical cylinder with a hemispherical dome supported on a foundation mat with a reactor cavity pit projection. CPNPP is a PWR which does not have a torus ring girder or downcomers; therefore, this item does not apply to CPNPP.

3.5.2.2.1.4. Loss of Prestress due to Relaxation, Shrinkage, Creep, and Elevated Temperature

Loss of prestress forces due to relaxation, shrinkage, creep, and elevated temperature for PWR prestressed concrete containments and BWR Mark II prestressed concrete containments is a Time-Limited Aging Analysis (TLAA) as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.5, "Concrete Containment Tendon Prestress Analysis," of this SRP-LR.

The CPNPP RCB is a Seismic Category I, fully continuous, steel-lined, reinforced concrete structure which consists of a vertical cylinder with a hemispherical dome supported on a foundation mat with a reactor cavity pit projection. CPNPP concrete Containment is not prestressed. Therefore, loss of prestress due to relaxation, shrinkage, creep, and elevated temperature does not apply to

CPNPP. Also, RG 1.103, RG 1.107, RG 1.90, and RG 1.35 are not applicable to CPNPP.

3.5.2.2.1.5. Cumulative Fatigue Damage

If included in the current licensing basis, fatigue analyses of suppression pool steel shells (including welded joints) and penetrations (including penetration sleeves, dissimilar metal welds, and penetration bellows) for all types of PWR and BWR containments and BWR vent header, vent line bellows, and downcomers are TLAAs as defined in 10 CFR 54.3. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.6, "Containment Liner Plates, Metal Containments, and Penetrations Fatigue Analysis," of this SRP-LR.

Fatigue analysis waivers are in place for the steel Containment liner plate and steel piping penetrations. The continued applicability of these waivers through the PEO are TLAAs and are addressed in Sections 4.6.1 and 4.6.2, respectively.

Larger Class metal Containment (MC) penetrations (e.g., air locks, hatch), as well as electrical penetration assemblies and the fuel transfer tube and sleeve, and piping penetrations for stainless steel lines (e.g., SI, RHR) do not have a fatigue analysis waiver. Stainless steel piping or flued heads connection to the steel penetration sleeve involve DMWs. Therefore, cracking due to cyclic loading (such as due to startups, shutdowns, or any earthquakes) is an AERM for the air locks, hatch, electrical penetration assemblies, fuel transfer tube, and piping penetration assemblies with stainless steel/DMWs as described in item number 3.5-1, 027 and will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50 Appendix J AMP through the PEO.

3.5.2.2.1.6. Cracking due to Stress Corrosion Cracking

Cracking due to stress corrosion cracking of stainless steel penetration bellows and dissimilar metal welds could occur in all types of PWR and BWR containments. The existing program relies on ASME Section XI, Subsection IWE and 10 CFR Part 50, Appendix J, to manage this aging effect. The GALL Report recommends further evaluation of additional appropriate examinations/evaluations implemented to detect these aging effects for stainless steel penetration bellows and dissimilar metal welds.

Cracking due to SCC is an applicable aging effect when stainless steel is exposed to temperatures in excess of 140ºF. As described in Table 3.5.2-1, CPNPP Containment piping penetration assemblies are carbon steel or stainless steel pipe passing through carbon steel sleeves with carbon steel or stainless steel flued head forgings. The sleeve and stainless steel process pipe/forging are connected via a DMW. The following piping penetration assemblies and the fuel transfer tube involve stainless steel piping and contain process fluid with temperatures above 140ºF and are therefore subject to SCC:

Penetration Number	Service
MII-1	Letdown Line to Letdown Heat Exchanger
MII-2	RHR from Hot Leg Loop #4
MII-3	RHR from Hot Leg Loop #1

Cracking due to SCC of stainless steel penetration assemblies and DMWs is managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP. The ASME Section XI, Subsection IWE AMP includes an enhancement for a one-time volumetric/surface examination of 20 percent of these twenty-two penetrations (i.e., five (5) inspections), if prompted by plant-specific OE. In addition, due to the high temperature, these penetrations are also leading indicators for cyclic load cracking of other susceptible piping penetrations.

3.5.2.2.1.7. Loss of Material (Scaling, Spalling) and Cracking due to Freeze-Thaw

Loss of material (scaling, spalling) and cracking due to freeze-thaw could occur in inaccessible areas of PWR and BWR concrete containments. The GALL Report recommends further evaluation of this aging effect for plants located in moderate to severe weathering conditions.

The regional climate of the CPNPP site is continental and is characterized by rapid changes in temperature, marked extremes, and large daily and annual temperature ranges. Typically, summer has over 100 days with temperatures of 90ºF or above and temperatures often exceed 100ºF. During the winter and early spring, CPNPP experiences outbreaks of polar continental air fronts with little associated weather. On occasion, artic air masses push through the region and cause cold spells that rarely last more than a few days. Normally, temperatures drop to 32ºF or below about 30 days each year. One or two occurrences of snow and one or two occurrences of sleet or freezing rain may be expected in both January and February, the coldest months. The annual mean temperature for the CPNPP site is 66ºF.

As stated in the CPNPP concrete specification, the concrete mix design provides for low permeability and adequate air entrainment such that the concrete has good freeze-thaw resistance. Air entrainment content conforms to the design requirements of ACI 211.1 and was determined by ASTM C231. Air entraining admixture shall be used to produce an air content of 3 percent ± 1 percent by volume, which may be increased to 4 percent ± 1 percent or 5 percent ± 1 percent for concrete with $1^{-1}/_{2}$-in max aggregate or ¾-in max aggregate, respectively, if needed for additional workability. No instances of concrete degradation due to freeze-thaw has been found at CPNPP.

CPNPP is located in a "moderate" weathering region as determined by ASTM C33-90 Figure 1. The exterior concrete of the RCB subject to the outdoor environment is not exposed to temperatures of 32ºF or less for sufficient durations that would cause freeze-thaw aging effects to occur. Therefore, loss of material (spalling, scaling) and cracking due to freeze-thaw do not require management for the CPNPP RCB or other structures.

3.5.2.2.1.8. Cracking due to Expansion from Reaction with Aggregates

Cracking due to expansion from reaction with aggregates could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. The GALL Report recommends further evaluation to determine if a plant-specific aging management program is required to manage this aging effect. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Concrete fine and coarse aggregates conform to ASTM C33, "Standard Specifications for Concrete Aggregates. Petrographic examinations of aggregates used in concrete were performed in accordance with ASTM C295, "Petrographic Examination of Aggregates for Concrete", and ASTM C289, "Potential Reactivity of Aggregates", to demonstrate that the aggregates do not adversely react within the concrete. In addition, concrete structures were constructed in accordance with ACI 318.

Although ASTM C295 and ASTM C289 were the acceptable testing standards at the time of plant construction to prevent reaction of aggregates, the NRC has issued IN 2011-20 addressing OE from Seabrook Station. Seabrook was also constructed in accordance with ASTM C295 and C289; however, it still experienced alkali-silica reaction (ASR) induced degradation.

Cracking and other indications of ASR associated with expansion due to reaction with aggregates has not been observed on the CPNPP RCB; however, the ASME Section XI, Subsection IWL (B.2.3.30) AMP and Structures Monitoring (B.2.3.34) AMP will continue to inspect and monitor for cracking and indications of ASR-induced degradation. CPNPP will also examine exposed portions of the below-grade concrete, when excavated for other reasons, through the Structures Monitoring (B.2.3.34) AMP.

3.5.2.2.1.9. Increase in Porosity and Permeability due to Leaching of Calcium Hydroxide and Carbonation

Increase in porosity and permeability due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of PWR and BWR concrete and steel containments. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

Leaching of calcium hydroxide and carbonation is observed on concrete that is alternatively wetted and dried. It becomes significant only if the concrete is exposed to flowing water. In the event that reinforced concrete is exposed to flowing water, such leaching is not significant if the concrete is constructed to ensure that it is dense, well cured, has low permeability, and that cracking is well controlled.

The CPNPP RCB is located in a region where weathering conditions are considered "moderate" as shown in ASTM C33-90, Figure 1. The RCB is exposed to precipitation. On average, there are 79 days of measurable (> 0.01-in) precipitation annually. The RCB is designed in accordance with ACI 318 and constructed in accordance with CC-4200 of ASME-ACI 359. The concrete mix uses Portland cement conforming to ASTM. Concrete aggregates conform to the requirements of ASTM C33. Materials for concrete used in the CPNPP RCB were specifically investigated, tested, and examined in accordance with pertinent ASTM standards. Concrete used in the RCB is constructed of a dense, well-cured concrete with an amount of cement suitable for strength development and achievement of a water-to-cement ratio that is characteristic of concrete having low permeability.

Normally inaccessible below grade concrete is visually examined when it is exposed by excavation (i.e., inspections of opportunity) for signs of degradation from aggressive chemical attack or corrosion of embedded steel. Accessible areas subject to similar conditions (material, environment, etc.) is evaluated instead of inaccessible areas. Inaccessible areas that are not inspected are documented and evaluated as such in the Structures Monitoring (B.2.3.34) AMP inspection report. The Structures Monitoring (B.2.3.34) AMP evaluates the acceptability of inaccessible areas when conditions exist in accessible areas that could indicate the presence of, or result in, degradation to such inaccessible areas.

There has been no plant-specific OE indicating leaching of calcium hydroxide or carbonation in accessible areas of the RCB. Furthermore, a portion of the reactor cavity pit foundation is below the water table and exposed to groundwater. Consistent with NUREG-1801 Section IX.D, both groundwater and rainwater are conservatively considered to be flowing water.

Therefore, increase in porosity and permeability due to leaching of calcium hydroxide and carbonation of the RCB exterior and below-grade concrete is an AERM for the PEO and will be managed by the ASME Section XI, Subsection IWL (B.2.3.30) AMP and Structures Monitoring (B.2.3.34) AMP through the PEO.

3.5.2.2.2. <u>Non-Containment Plant Structures</u>

At CPNPP, the non-Containment plant structures fall into the following groups (Groups 2 and 9 structures are not applicable at CPNPP, which is a PWR). CPNPP does not have a shield building for a MC but has a concrete containment with a metal liner that is addressed in Section 3.5.2.2.1:

- Group 1: ECB.
- Group 3: AB, DGBs, SGBs, Switchgear Buildings, Switchyard Structures, TBs, Yard Structures
- Group 4: Containment internal structures – Addressed elsewhere (PSW, major equipment supports, and refueling components are addressed in Section 3.5.2.2.1 and component support, crane, and fire barrier commodity groups are addressed in Sections 3.5.2.1.13, 3.5.2.1.14, and 3.5.2.1.15)
- Group 5: FB
- Group 6: SSI and Dam, SWIS
- Group 7: CST, RMWST, RWST, and concrete missile barriers
- Group 8: Missile doors (The steel FWSTs are addressed in Section 3.5.2.1.11 whereas the foundations are considered with Group 3).

The following sections provide the CPNPP disposition to those areas that warrant further evaluation. *Italicized* text is taken from NUREG-1800.

3.5.2.2.2.1. <u>Aging Management of Inaccessible Areas</u>

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below grade inaccessible concrete areas of Groups 1-3, 5 and 7-9 structures. The GALL Report recommends further evaluation of this aging effect for inaccessible areas of these Groups of structures for plants located in moderate to severe weathering conditions.*

As summarized in item 3.5-1, 042, non-Containment structures at CPNPP consist of Groups 1, and 3 through 8. CPNPP is located in a region where weathering conditions are considered moderate, as shown in ASTM C33-90,

Figure 1. The concrete for the in-scope structures has reached its design strength, and the winter design temperature is 20°F. The Materials, Quality Control, and Special Construction Techniques state that the concrete met the standard code requirements. As stated in the CPNPP concrete specification, the mix design provides for low permeability and adequate air entrainment such that the concrete has good freeze-thaw resistance. Air entrainment content conformed to the design requirements of ACI 211.1 and was determined by ASTM C231.

OE has not identified any loss of material (spalling, scaling) and cracking due to freeze-thaw of reinforced concrete structures within the scope of LR. The CPNPP Structures Monitoring (B.2.3.34) AMP does include inspection of concrete in the accessible areas. The condition of accessible and above grade concrete is used as an indicator for the condition of the inaccessible and below grade structural components and provides reasonable assurance that degradation of inaccessible structural components will be detected before a loss of intended function.

Also, freeze-thaw damage is not significant for reinforced concrete in foundations, and in above and below grade exterior concrete, for plants located in areas in which weathering conditions are considered moderate (100–500 day-in./yr.), provided that the concrete mix design meets the air content (entrained air 3-6 percent) and water-to-cement ratio (0.35–0.45) specified in ACI 318-63 or ACI 349-85. CPNPP structures are located in a region where weathering conditions are considered moderate and CPNPP concrete specifications meet the mix design requirements for the air content and water-to-cement standards.

However, CPNPP will examine exposed portions of the below-grade concrete, when excavated for any reason, in accordance with the Structures Monitoring (B.2.3.34) AMP, which would identify loss of material and cracking should freeze-thaw occur in rare instances in the moderate weathering conditions.

2. *Cracking due to expansion and reaction with aggregates could occur in below-grade inaccessible concrete areas for Groups 1-5 and 7-9 structures. The GALL Report recommends further evaluation of inaccessible areas of these Groups of structures if concrete was not constructed in accordance with the recommendations in the GALL Report.*

As summarized in item 3.5-1, 043, non-Containment structures at CPNPP consist of Groups 1, and 3 through 8. Concrete fine and coarse aggregates conform to ASTM C33. Petrographic examinations of aggregates used in concrete were performed in accordance with ASTM C295, “Petrographic Examination of Aggregates for Concrete”, and ASTM C289, “Potential Reactivity of Aggregates”, to demonstrate that the aggregates do not adversely react within the concrete. In addition, concrete structures were constructed in accordance with ACI 318-71. As stated in the CPNPP specification for concrete, potential reactivity of the aggregate has been considered in the design of the concrete mix by the required use of low alkali cement. The results of the tests for Potential Reactivity of Aggregates (ASTM C289) were provided to the Engineer who monitored changes in potential reactivity and assessed their influence on the concrete mix design. The frequency of tests in accordance with ASTM C289 was directed by the Engineer.

Cracking and other indications of ASR associated with expansion due to reaction with aggregates has not been observed on CPNPP concrete structures. Nevertheless, the Structures Monitoring (B.2.3.34) AMP continues to inspect and monitor concrete structures for cracking, including hairline and patterned cracking, that are typical evidence of reaction with aggregates, such as ASR. CPNPP also examines exposed portions of below-grade (inaccessible) concrete, when excavated for any reason, in accordance with the Structures Monitoring (B.2.3.34) AMP. As such, cracking due to expansion and reaction with aggregates in below-grade inaccessible concrete areas for Groups 1, and 3 through 8 structures is managed the Structures Monitoring (B.2.3.34) AMP.

3. *Cracking and distortion due to increased stress levels from settlement could occur in below-grade inaccessible concrete areas of structures for all Groups, and reduction in foundation strength, and cracking due to differential settlement and erosion of porous concrete sub foundations could occur in below-grade inaccessible concrete areas of Groups 1-3, 5 -9 structures. The existing program relies on structure monitoring programs to manage these aging effects. Some plants may rely on a de-watering system to lower the site ground water level. If the plant's CLB credits a de-watering system, the GALL Report recommends verification of the continued functionality of the de-watering system during the period of extended operation. The GALL Report recommends no further evaluation if this activity is included in the scope of the applicant's structures monitoring program.*

Settlement is based directly on the physical properties of soil and a structure's foundation material. Cracks, distortion, and increase in component stresses due to settlement of Seismic Category I concrete foundations are considered in the Structures Monitoring (B.2.3.34) AMP. With the exception of the Category I tanks and pipe tunnels, the Seismic Category I concrete structure walls and columns are supported on thick continuous concrete base mats which rest on the rock subgrade.

As summarized in item 3.5-1, 044, CPNPP plant structures are founded on competent rock. Settlement monitoring and structural inspections indicate no visible evidence of uneven or excessive settlement since construction of the station. Differential settlement of structures, which would be evidenced by cracking or warping of structures and structural components is not a problem at CPNPP. As stated in the Structural Monitoring Inspection Guide, settlement markers are located on exterior walls of various buildings, measurements are taken and compared to previous readings.

CPNPP does not rely on a de-watering system to lower the site groundwater level. No groundwater was encountered during excavation and construction of the plant structures. However, during design validation efforts it was determined that perched water may exist at elevations higher than 775-ft. There has been no dewatering at the site during or after construction.

The Structures Monitoring (B.2.3.34) AMP continues to inspect and monitor concrete structures within the scope of LR. Therefore, cracking and distortion due to settlement is managed by the Structures Monitoring (B.2.3.34) AMP, but porous foundations and dewatering do not exist at CPNPP.

4. *Increase in porosity and permeability, and loss of strength due to leaching of calcium hydroxide and carbonation could occur in below-grade inaccessible concrete areas of Groups 1-5 and 7-9 structures. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions.*

Groups 1, and 3 through 8 structures at CPNPP are designed in accordance with ACI 318-71 and constructed in accordance with ACI 301-72 using ingredients/materials conforming to ACI and ASTM standards. Concrete aggregates conform to the requirements of ASTM C-33-74 (fine and coarse aggregate). Materials for concrete used in CPNPP concrete structures and components were specifically investigated, tested, and examined in accordance with pertinent ASTM standards. Concrete structures and CC are constructed of a dense, well-cured concrete with an amount of cement suitable for strength development and achievement of a water-to-cement ratio that is characteristic of concrete having low permeability.

As summarized in item 3.5-1, 047, the ECB, SGBs, and TBs are the buildings in the scope of LR whose foundation extends below the water table and are exposed to groundwater that is more than absorbed surface or perched water. Recent monitoring of the groundwater chemistry at CPNPP has revealed that the groundwater is not aggressive (Chloride <500 ppm, Sulfates <1500 ppm, and Ph >5.5) with respect to chlorides, pH, or sulphates. Therefore, below-grade inaccessible concrete for the ECB, SGBs, and TBs are exposed to conditions that may result in increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide or carbonation. Conversely, the below grade portions of the AB, DGBs, FB, switchgear buildings, yard structures, and switchyard structures are located above the water table and leaching is not a concern.

Leaching of calcium hydroxide is commonly applicable for a flowing water environment. Consistent with NUREG-1801, ‘water-flowing’ can include rainwater or groundwater. Leaching of calcium hydroxide or carbonation has not occurred for above-grade concrete at CPNPP. Therefore, increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide or carbonation could occur for exterior above-grade concrete due to water-flowing from heavy rains and for below-grade portions of the ECB, SGBs, and TBs. However, the Structures Monitoring (B.2.3.34) AMP continues to inspect and monitor concrete structures within the scope of LR. CPNPP also examines exposed portions of below-grade (inaccessible) concrete, when excavated for any reason, in accordance with the Structures Monitoring (B.2.3.34) AMP.

3.5.2.2.2.2. <u>Reduction of Strength and Modulus due to Elevated Temperature</u>

Reduction of strength and modulus of concrete due to elevated temperatures could occur in PWR and BWR Group 1-5 concrete structures. For any *concrete elements that exceed specified temperature limits, further evaluations are recommended. Appendix A of ACI 349-85 specifies the concrete temperature limits for normal operation or any other long-term period. The temperatures shall not exceed 66°C (150°F) except for local areas, which are allowed to have increased temperatures not to exceed 93°C (200°F). The GALL Report recommends further evaluation of a plant-specific program if any portion of the safety-related and other concrete structures exceeds specified temperature limits, i.e., general area temperature greater than 66°C (150°F) and local area temperature greater than 93°C (200°F). Higher temperatures may be allowed if tests and/or calculations are provided to evaluate the reduction in strength and modulus of elasticity and these reductions are applied to the design calculations. The acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

As summarized in item 3.5-1, 048, CPNPP Structures other than Containment are not subject to area temperatures greater than 150°F as shown in FSAR Table 9.4-2. Furthermore, the ECB (Group 1) does not have high temperature piping entering or passing through it such that local concrete temperatures remain well below 150°F. Similarly, the Switchyard Structures and Yard Structures (Group 3), do not have any high temperature piping systems routed near them. The refuel floor and spent fuel storage pool are part of the FB (Group 5). The SFP bulk water temperatures are maintained at less than 150°F for normal operation based on decay heat generation from a normal full core offload at 125 hours after shutdown, plus decay heat from the opposite unit's last refueling discharge plus decay heat from fuel assemblies from a maximum number of previous refueling in both pools. PSW concrete temperatures inside Containment (Group 4) are addressed in Section 3.5.2.2.1.2 along with Containment penetrations.

Where any type of insulated piping goes through a sealed penetration or sleeve, the insulation is removed 1" from each side of the penetration. Where any type insulation goes through an unsealed penetration or sleeve, a minimum of 2" clearance is maintained between the outside diameter of the insulation and the inside diameter of the sleeve.

The AB, and SGBs (Group 3) do have high temperature lines that enter or pass-through them, such as Main Steam, Feedwater, and Steam Generator Blowdown. High temperature lines are also routed on the roof of the Switchgear buildings to the TBs (Group 3). Main Steam (MS) lines enter the SGBs through the containment penetrations. Each of the four MS lines inside the SGBs are in their own compartment and have adequate separation. The MS lines are routed inside the SGBs through open sleeves with a minimum clearance. The MS lines leave the SGB onto the Switchgear building roof also through open sleeves with a minimum clearance on the external walls of the SGB. The open sleeves provided for routing these high temperature lines prevent the surrounding concrete wall from direct contact with the pipes and hence the concrete temperature will not exceed 200°F. The Main steam lines over the Switchgear building are supported above the Switchgear Building roof slab approximately 4-ft and hence the concrete temperature will not exceed 200°F. For the AB, SGBs and TBs, the combination of building ventilation systems and the air gap for unsealed penetrations has been adequate to maintain local concrete temperatures below 200°F for roof/wall penetrations during normal plant operation.

The diesel generators are tested monthly, and operated infrequently for losses of offsite power, such that the fire bricks and mortar between each DG silencer and the roof/wall concrete of the DGBs (Group 3) is subject to high temperature DG exhaust for the brief duration of the test/run. For the DGBs the combination of building ventilation systems and the air gap for unsealed penetrations, as well as the fire bricks, has been adequate to maintain local concrete temperatures below 200°F for the roof, wall, and penetrations during normal plant operation. The Masonry Walls (B.2.3.33) AMP will manage the condition of the fire bricks and mortar during the period of extended operation, and thereby the condition of the underlying concrete and roofing membrane.

Furthermore, plant operating experience has not identified elevated general and local area temperature as a concern for concrete structural components. Therefore, reduction of strength and modulus of concrete due to elevated temperatures are not expected to occur at CPNPP and do not require management for the AB and other (non-Containment) CPNPP structures.

3.5.2.2.2.3. Aging Management of Inaccessible Areas for Group 6 Structures

The GALL Report recommends further evaluation for inaccessible areas of certain Group 6 structure/aging effect combinations as identified below, whether or not they are covered by inspections in accordance with the GALL Report, Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants," or FERC/US Army Corp of Engineers dam inspection and maintenance procedures.

1. *Loss of material (spalling, scaling) and cracking due to freeze-thaw could occur in below grade inaccessible concrete areas of Group 6 structures. The GALL Report recommends further evaluation of this aging effect for inaccessible areas for plants located in moderate to severe weathering conditions.*

As summarized in item 3.5-1, 049, CPNPP structures, including the SWIS, are located in a region where weathering conditions are considered moderate, as shown in ASTM C33-90, Figure 1. The concrete for the in-scope structures has reached its design strength, and the winter design temperature is 20°F. The concrete structures are designed and constructed in accordance with ACI 318 and ACI 301. The design provides for low permeability and adequate air entrainment such that the concrete has good freeze-thaw resistance. Air entrainment content conformed to the design requirements of ACI 211.1 and was determined by ASTM C231. The concrete mix design has adequate resistance to freezing and thawing. Furthermore, the Texas climate is too warm to allow the development of significant ice on any lake. There are no records of any major river in Texas freezing over at any time, so the possibility of ice flooding can be discounted. Therefore, the loss of material (spalling, scaling) and cracking due to freeze-thaw does not apply to the CPNPP SWIS or SSI and Dam.

Furthermore, OE has not identified loss of material (spalling, scaling) and cracking due to freeze-thaw of the SWIS, which is a reinforced concrete structure within the scope of LR. However, the RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP does include inspections in the accessible areas of the SWIS (intake bay) for other aging effects. Similarly, the Structures Monitoring (B.2.3.34) AMP includes inspections in accessible (above-grade/water-level) areas of the SWIS, CPNPP will examine inaccessible areas or components as they become accessible for other reasons.

2. *Cracking due to expansion and reaction with aggregates could occur in below-grade inaccessible reinforced concrete areas of Group 6 structures. The GALL Report recommends further evaluation to determine if a plant-specific aging management program is required to manage this aging effect. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

Concrete fine and coarse aggregates conform to ASTM C33. Petrographic examinations of aggregates used in concrete were performed in accordance with ASTM C295, "Petrographic Examination of Aggregates for Concrete", and ASTM C289, "Potential Reactivity of Aggregates", to demonstrate that the aggregates do not adversely react within the concrete. In addition, concrete structures were constructed in accordance with ACI 318. As stated in the CPNPP specification for concrete, potential reactivity of the aggregate has been considered in the design of the concrete mix by the required use of low alkali cement. The results of the tests for potential reactivity of aggregates (ASTM C289) were provided to the Engineer who monitored changes in potential reactivity and assessed their influence on the concrete mix design. The frequency of tests in accordance with ASTM C289 was directed by the Engineer.

As summarized in item 3.5-1, 050, cracking and other indications of ASR associated with expansion due to reaction with aggregates has not been observed on CPNPP concrete structures, including the SWIS. However, based on experience at other sites, the potential for reaction with aggregates, such as ASR, cannot be eliminated for the PEO. As such, cracking due to expansion and reaction with aggregates is an applicable aging effect in below-grade inaccessible concrete areas for CPNPP Group 6 structures and will be managed by the RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP and the Structures Monitoring (B.2.3.34) AMP.

3. *Increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide and carbonation could occur in inaccessible areas of concrete elements of Group 6 structures. The GALL Report recommends further evaluation if leaching is observed in accessible areas that impact intended functions. Acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).*

As summarized in item 3.5-1, 051, structures at CPNPP including Group 6 structures are designed in accordance with ACI 318-71 and constructed in accordance with ACI 301-72 using ingredients/materials conforming to ACI and ASTM standards. Concrete aggregates conform to the requirements of

ASTM C-33-74 (fine and coarse aggregate). Materials for concrete used in CPNPP concrete structures and components were specifically investigated, tested, and examined in accordance with pertinent ASTM standards. Cracking is controlled through proper arrangement and distribution of reinforcing steel. Concrete structures and CC are constructed of a dense, well-cured concrete with an amount of cement suitable for strength development and achievement of a water-to-cement ratio that is characteristic of concrete having low permeability. This is consistent with the recommendations and guidance provided by ACI 201.2R. However, the below grade surfaces of the SWIS are exposed to raw water and groundwater below the water table, both of which are considered water-flowing for LR. Therefore, a change in material properties (described as increase in porosity and permeability, and loss of strength) due to leaching of calcium hydroxide and carbonation in below-grade concrete may be an aging effect for the CPNPP SWIS. Therefore, the RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP and the Structures Monitoring (B.2.3.34) AMP will manage the aging effect.

3.5.2.2.2.4. Cracking due to Stress Corrosion Cracking, and Loss of Material due to Pitting and Crevice Corrosion

Cracking due to stress corrosion cracking and loss of material due to pitting and crevice corrosion could occur for Group 7 and 8 stainless steel tank liners exposed to standing water. The GALL Report recommends further evaluation of plant-specific programs to manage these aging effects. The acceptance criteria are described in Branch Technical Position RLSB-1 (Appendix A.1 of this SRP-LR).

As summarized in item 3.5-1, 052, the RWST, RMWST, and CST for each unit are missile protected, Seismic Category I concrete tanks with stainless steel liners. These Group 7 structures have concrete roofs, with manways and vents. The stainless steel liners inside the Seismic Category 1 tanks are anchored to the concrete. This configuration precludes water getting between the concrete and stainless steel liner, and the concrete forms a tight seal with the liner (walls and bottom). The stainless steel liners are evaluated as tanks within the following systems:

- RWST - CSS
- RMWST - DRMWS
- CST – AFWS

Loss of material due to pitting and crevice corrosion in the treated borated water or treated water contained in these Group 7 tanks will be managed by the Water Chemistry (B.2.3.2) AMP and One-Time Inspection (B.2.3.19) AMP. Cracking due to SCC of stainless steel components in these environments does not require management as the temperatures of the water is less than 140°F. The normal operating environment for the RWST, RMWST, and CST is at ambient temperature.

3.5.2.2.2.5. Cumulative Fatigue Damage Due to Fatigue

Fatigue of component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports is a TLAA as defined in 10 CFR 54.3 only if a CLB fatigue analysis exists. TLAAs are required to be evaluated in accordance with 10 CFR 54.21(c). The evaluation of this TLAA is addressed separately in Section 4.3, "Metal Fatigue Analysis," of this SRP-LR.

As summarized in item 3.5-1, 053, there is no fatigue analysis for cumulative fatigue damage due to time-dependent fatigue, cyclic loading, or cyclical displacement of component support members, anchor bolts, and welds for Groups B1.1, B1.2, and B1.3 component supports at CPNPP requiring evaluation as TLAA. Cumulative fatigue damage due to cyclic loading is an applicable aging effect for cranes (overhead heavy and light load (related to refueling) handling systems) at CPNPP and is addressed in Section 4.7.4, "Crane Load Cycle Limits".

3.5.2.2.2.6. Quality Assurance for Aging Management of Non-nuclear Safety Related Components

QA provisions applicable to LR are discussed in Section B.1.3.

3.5.2.3. Time-Limited Aging Analysis

The TLAAs identified below are associated with the Containment, Structures, and Component Supports:

- Section 4.3, "Metal Fatigue"
- Section 4.6, "Containment Liner Plate, Metal Containments, and Penetrations Fatigue Analyses"
- Section 4.7.4, "Crane Load Cycle Limit"
- Section 4.7.6, "Protective Coatings"

Note - As discussed in Section 3.5.2.2.1.4 and item 3.5-1, 008, the CPNPP RCB does not use prestressed tendons.

3.5.3. Conclusion

The Containments, Structures, and Component Supports that are subject to AMR have been identified in accordance with the requirements of 10 CFR 54.4. The AMPs selected to manage aging effects for the Containments, Structures, and Component Supports are identified in the summaries in Section 3.5.2.1 above.

A description of these AMPs is provided in Appendix B, along with the demonstration that the identified aging effects will be managed for the PEO.

Therefore, based on the conclusions provided in Appendix B, the effects of aging associated with the Containments, Structures, and Component Supports components will be adequately managed so that there is reasonable assurance that the intended functions are maintained consistent with the CLB during the PEO.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 001	Concrete: dome; wall; basemat; ring girders; buttresses, Concrete elements, all	Cracking and distortion due to increased stress levels from settlement	Chapter XI.S2, "ASME Section XI, Subsection IWL" or Chapter XI.S6, "Structure Monitoring" If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See SRP subsection 3.5.2.2.1.1)	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage cracking and distortion due to settlement. CPNPP does not rely upon a de-watering system to control settlement. Further evaluation is contained in Section 3.5.2.2.1.1.
3.5-1, 002	Concrete: foundation; subfoundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete subfoundation	Chapter XI.S6, "Structures Monitoring" If a de-watering system is relied upon for control of erosion, then the licensee is to ensure proper functioning of the dewatering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See SRP subsection 3.5.2.2.1.1)	Not applicable. The RCB is not founded on a porous concrete subfoundation and therefore, this aging effect and mechanism is not applicable to CPNPP. Further evaluation is contained in Section 3.5.2.2.1.1.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 003	Concrete: dome; wall; basemat; ring girders; buttresses, Concrete: containment; wall; basemat, Concrete: basemat, concrete fill-in annulus	Reduction of strength and modulus due to elevated temperature (>150°F general; >200°F local)	A plant-specific aging management program is to be evaluated.	Yes, if temperature limits are exceeded (See SRP subsection 3.5.2.2.1.2)	Not applicable. The average temperature inside Containment at CPNPP is maintained less than 120ºF. Localized concrete temperatures exceeding 200ºF have not been reported. Further evaluation is contained in Section 3.5.2.2.1.2.
3.5-1, 004	This line item only applies to BWRs.				
3.5-1, 005	Steel elements (inaccessible areas): liner; liner anchors; integral attachments, Steel elements (inaccessible areas): suppression chamber; drywell; drywell head; embedded shell; region shielded by diaphragm floor (as applicable)	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE" and Chapter XI.S4, "10 CFR Part 50, Appendix J"	Yes, if corrosion is indicated from the IWE examinations (See SRP subsection 3.5.2.2.1.3.1)	Consistent with NUREG-1801. The ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP will be used to manage loss of material of the steel containment liner plate, liner plate anchors, and integral attachments. Further evaluation is contained in Section 3.5.2.2.1.3.1. See also item 3.5-1, 035.
3.5-1, 006	This line item only applies to BWRs.				
3.5-1, 007	This line item only applies to BWRs.				
3.5-1, 008	Prestressing system: tendons	Loss of prestress due to relaxation; shrinkage; creep; elevated temperature	Yes, TLAA	Yes, TLAA (See SRP subsection 3.5.2.2.1.4)	Not applicable. CPNPP has a steel liner reinforced concrete containment structure. The RCB does not use prestressed tendons. Further evaluation is contained in Section 3.5.2.2.1.4.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 009	Penetration sleeves; penetration bellows, Steel elements: torus; vent line; vent header; vent line bellows; downcomers, Suppression pool shell; unbraced downcomers, Steel elements: vent header; downcomers	Cumulative fatigue damage due to fatigue (Only if CLB fatigue analysis exists)	Yes, TLAA	Yes, TLAA (See SRP subsection 3.5.2.2.1.5)	Fatigue is an aging effect for steel piping (mechanical) penetration assemblies and is assessed by a TLAA (waiver). Other penetrations are addressed in items 3.5-1, 010 and 3.5-1, 027 below. Further evaluation is documented in Section 3.5.2.2.1.5.
3.5-1, 010	Penetration sleeves; penetration bellows	Cracking due to stress corrosion cracking	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	Yes, detection of aging effects is to be evaluated (See SRP subsection 3.5.2.2.1.6)	Consistent with NUREG-1801. The ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP will be used to manage cracking of high-temperature stainless steel and DMW mechanical (piping/transfer tube) penetration components. Further evaluation is contained in Section 3.5.2.2.1.6.
3.5-1, 011	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): dome; wall; basemat	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is needed for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr) (NUREG-1557).	Yes, for plants located in moderate to severe weathering conditions (See SRP subsection 3.5.2.2.1.7)	Not applicable. CPNPP is located in a “moderate” weathering region as determined by ASTM C33-90 Figure 1. The exterior concrete of the RCB subject to the outdoor environment is not exposed to temperatures of 32 ºF or less for sufficient durations that would cause freeze-thaw aging effects to occur. Further evaluation is contained in Section 3.5.2.2.1.7.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 012	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): containment; wall; basemat, Concrete (inaccessible areas): basemat, concrete fill-in annulus	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated function (See SRP subsection 3.5.2.2.1.8)	Consistent with NUREG-1801. Cracking associated with expansion due to reaction with aggregates has not been observed on the CPNPP RCBs. However, the ASME Section XI, Subsection IWL (B.2.3.30) AMP and Structures Monitoring (B.2.3.34) AMP will continue to inspect and monitor for cracking and indications of ASR-induced or similar degradation. Further evaluation is contained in Section 3.5.2.2.1.8.
3.5-1, 013	Concrete (inaccessible areas): basemat, Concrete (inaccessible areas): dome; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See SRP subsection 3.5.2.2.1.9)	Not used. Inaccessible portions of the foundation mat of the concrete RCB that are exposed to water – flowing (groundwater) are addressed in item 3.5-1, 014 below. Further evaluation is contained in Section 3.5.2.2.1.9.
3.5-1, 014	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): containment; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See SRP subsection 3.5.2.2.1.9)	Consistent with NUREG-1801. Increase in porosity and permeability and loss of strength due to leaching of calcium hydroxide and carbonation in inaccessible areas of the RCBs are applicable aging effects and will be managed by the ASME Section XI, Subsection IWL (B.2.3.30) AMP and Structures Monitoring (B.2.3.34) AMP. Further evaluation is contained in Section 3.5.2.2.1.9.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 015	Concrete (accessible areas): basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	Not used. The reinforced concrete foundation/mat for the RCBs is completely below-grade and is not accessible.
3.5-1, 016	Concrete (accessible areas): basemat, Concrete: containment; wall; basemat	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S2, “ASME Section XI, Subsection IWL,” or Chapter XI.S6, "Structures Monitoring"	No	Not applicable. Increase in porosity and permeability, cracking, and loss of material due to aggressive chemical attack is not an applicable aging effect/mechanism requiring management as the concrete is not exposed to acidic solutions with a pH < 5.5, chloride solutions > 500ppm, or sulfate solutions > 1500ppm.
3.5-1, 017	This line item only applies to BWRs.				
3.5-1, 018	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): basemat	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	Not applicable. CPNPP is located in a “moderate” weathering region as determined by ASTM C33-90 Figure 1. The exterior concrete of the RCB subject to the outdoor environment is not exposed to temperatures of 32 ºF or less for sufficient durations that would cause freeze-thaw aging effects to occur.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 019	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): basemat, Concrete (accessible areas): containment; wall; basemat, Concrete (accessible areas): basemat, concrete fill-in annulus	Cracking due to expansion from reaction with aggregates	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	Consistent with NUREG-1801. Cracking associated with expansion due to reaction with aggregates has not been observed on the CPNPP RCB; however, the ASME Section XI, Subsection IWL (B.2.3.30) AMP will continue to inspect and monitor for cracking and indications of ASR-induced degradation.
3.5-1, 020	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (accessible areas): containment; wall; basemat	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	Consistent with NUREG-1801. Increase in porosity and permeability due to leaching of calcium hydroxide and carbonation in accessible areas of the RCBs, exposed to heavy precipitation/drainage, is an applicable aging effect and mechanism and will be managed by the ASME Section XI, Subsection IWL (B.2.3.30) AMP.
3.5-1, 021	Concrete (accessible areas): dome; wall; basemat; ring girders; buttresses; reinforcing steel, Concrete (accessible areas): basemat; reinforcing steel, Concrete (accessible areas): dome; wall; basemat; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, "ASME Section XI, Subsection IWL"	No	Consistent with NUREG-1801. Cracking, loss of bond, and loss of material due to corrosion of embedded steel are applicable aging effects and will be managed by the ASME Section XI, Subsection IWL (B.2.3.30) AMP.
3.5-1, 022	This line item only applies to BWRs.				

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 023	Concrete (inaccessible areas): basemat; reinforcing steel, Concrete (inaccessible areas): dome; wall; basemat; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, “ASME Section XI, Subsection IWL,” or Chapter XI.S6, "Structures Monitoring"	No	Not used. CPNPP Containment is a steel lined reinforced concrete structure. This item is only applicable to steel containments. Cracking, loss of bond and loss of material for inaccessible Containment concrete is addressed in item 3.5-1, 025 below.
3.5-1, 024	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses, Concrete (inaccessible areas): basemat, Concrete (accessible areas): dome; wall; basemat	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S2, “ASME Section XI, Subsection IWL,” or Chapter XI.S6, "Structures Monitoring"	No	Not applicable. Increase in porosity and permeability, cracking, and loss of material due to aggressive chemical attack is not an applicable aging mechanism requiring management as the concrete is not exposed to acidic solutions with a pH < 5.5, chloride solutions > 500ppm, or sulfate solutions > 1500ppm.
3.5-1, 025	Concrete (inaccessible areas): dome; wall; basemat; ring girders; buttresses; reinforcing steel	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S2, “ASME Section XI, Subsection IWL,” or Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. Cracking, loss of bond, and loss of material due to corrosion of embedded steel is an applicable aging effect and will be managed by the ASME Section XI, Subsection IWL (B.2.3.30) AMP.
3.5-1, 026	Moisture barriers (caulking, flashing, and other sealants)	Loss of sealing due to wear, damage, erosion, tear, surface cracks, or other defects	Chapter XI.S1, “ASME Section XI, Subsection IWE”	No	Consistent with NUREG-1801. Loss of sealing due to wear, damage, erosion, tear, surface cracks, or other defects of the Containment liner moisture barrier are applicable aging effects and will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 027	Penetration sleeves; penetration bellows, Steel elements: torus; vent line; vent header; vent line bellows; downcomers, Suppression pool shell	Cracking due to cyclic loading (CLB fatigue analysis does not exist)	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	No	Consistent with NUREG-1801. Cracking to due cyclic loading is an applicable aging effect for the Containment airlocks, hatch, electrical penetrations, fuel transfer tube, and (mechanical) piping penetrations that involve stainless steel and DMWs. A CLB fatigue analysis does not exist for these penetrations. Cyclic load cracking will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP. Refer to item 3.5-1, 009 for steel piping (mechanical) penetration assemblies (for which a CLB fatigue waiver exists). Additionally, piping penetrations addressed by item 3.5-1, 010 are also leading indicators for cyclic load cracking, due to the higher temperatures during normal operation than other Containment penetrations without a CLB fatigue waiver.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 028	Personnel airlock, equipment hatch, CRD hatch	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Consistent with NUREG-1801. Loss of material due to general, pitting, and crevice corrosion is an applicable aging effect for the emergency airlock, personnel airlock, equipment hatch, outage equipment hatch cover and all associated accessories. Loss of material for these penetrations will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP. Loss of material for the outer cover for the equipment hatch will be managed by the Structures Monitoring (B.2.3.34) AMP.
3.5-1, 029	Personnel airlock, equipment hatch, CRD hatch: locks, hinges, and closure mechanisms	Loss of leak tightness due to mechanical wear of locks, hinges and closure mechanisms	Chapter XI.S1, "ASME Section XI, Subsection IWE," and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Consistent with NUREG-1801. Loss of leak tightness due to mechanical wear is an applicable aging effect for the emergency airlock, personnel airlock, equipment hatch, and all associated accessories. Loss of material for these penetrations will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 030	Pressure-retaining bolting	Loss of preload due to self-loosening	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, "10 CFR Part 50, Appendix J"	No	Consistent with NUREG-1800. Loss of preload due to self-loosening is an applicable aging effect for the Containment closure bolting. Loss of preload will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP.
3.5-1, 031	Pressure-retaining bolting, Steel elements: downcomer pipes	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, “ASME Section XI, Subsection IWE”	No	Consistent with NUREG-1800. Loss of material is an applicable aging effect for the steel Containment closure bolting. Loss of material will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP.
3.5-1, 032	Prestressing system: tendons; anchorage components	Loss of material due to corrosion	Chapter XI.S2, “ASME Section XI, Subsection IWL”	No	Not applicable. CPNPP has a steel liner reinforced concrete containment structure. The RCBs do not use prestressed tendons.
3.5-1, 033	Seals and gaskets	Loss of sealing due to wear, damage, erosion, tear, surface cracks, or other defects	Chapter XI.S4, “10 CFR Part 50, Appendix J "	No	Consistent with NUREG-1801. Loss of sealing associated with seals for the emergency airlock, personnel airlock, and equipment hatch, as well as the outage equipment hatch cover, or other penetrations is an applicable aging effect and will be managed by the 10 CFR Part 50, Appendix J (B.2.3.32) AMP.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 034	Service Level I coatings	Loss of coating integrity due to blistering, cracking, flaking, peeling, or physical damage	Chapter XI.S8, "Protective Coating Monitoring and Maintenance"	No	Consistent with NUREG-1801. Loss of coating integrity due to blistering, cracking, flaking, peeling, or physical damage will be managed by the Protective Coating Monitoring and Maintenance (B.2.3.36) AMP.
3.5-1, 035	Steel elements (accessible areas): liner; liner anchors; integral attachments, Penetration sleeves, Steel elements (accessible areas): drywell shell; drywell head; drywell shell in sand pocket regions; Steel elements (accessible areas): suppression chamber; drywell; drywell head; embedded shell; region shielded by diaphragm floor (as applicable), Steel elements (accessible areas): drywell shell; drywell head	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S1, “ASME Section XI, Subsection IWE,” and Chapter XI.S4, “10 CFR Part 50, Appendix J”	No	Consistent with NUREG-1801. Loss of material due to general, pitting, and crevice corrosion is an applicable aging effect for the Containment liner plate (and associated attachments), penetration assemblies, fuel transfer tube penetration sleeve and leak chase channels. Loss of material will be managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP and 10 CFR Part 50, Appendix J (B.2.3.32) AMP. Threaded leak chase channel screw caps in depressions in the operating floor are accessible and managed by the ASME Section XI, Subsection IWE (B.2.3.29) AMP. A plant-specific note is used.
3.5-1, 036	This line item only applies to BWRs.				
3.5-1, 037	This line item only applies to BWRs.				
3.5-1, 038	This line item only applies to BWRs.				
3.5-1, 039	This line item only applies to BWRs.				

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 040	This line item only applies to BWRs.				
3.5-1, 041	This line item only applies to BWRs.				
3.5-1, 042	Groups 1-3, 5, 7- 9: Concrete (inaccessible): foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is required for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr.) (NUREG-1557)	Yes, for plants located in moderate to severe weathering conditions (See SRP subsection 3.5.2.2.2.1.1)	Not applicable. Group 2 and 9 structures are not present at CPNPP. CPNPP is located in a moderate weathering region with concrete, for group 1, 3-5 and 7 structures, that meet the air-entrainment and water-cement-ratio of ACI 318-71. Further evaluation is documented in subsection 3.5.2.2.2.1, item 1. In addition, the Structures Monitoring (B.2.3.34) AMP is credited with management of other aging effects for the concrete foundations of group 1, 3-5, and 7 structures.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 043	All Groups except Group 6: Concrete (inaccessible): all	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated (See SRP subsection 3.5.2.2.2.1.2)	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP is credited with managing cracking due to reaction with aggregates (such as ASR), for CPNPP group 1, 3-5, and 7 structures, including inaccessible areas. Consistent with the OE reflected in SLR-ISG-2021-03-STRUCTURES, a plant-specific AMP is not required. The Structures Monitoring (B.2.3.34) AMP includes opportunistic examination of below-grade inaccessible concrete areas based on conditions in accessible areas. Further evaluation is documented in subsection 3.5.2.2.2.1, item 2.
3.5-1, 044	All Groups: concrete: all	Cracking and distortion due to increased stress levels from settlement	Chapter XI.S6, “Structures Monitoring” If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de- watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See SRP subsection 3.5.2.2.2.1.3)	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP is credited to manage cracking and distortion of below-grade exterior and foundation concrete, manholes, handholes, and duct banks exposed to soil. CPNPP does not rely upon a de-watering system to control settlement. Further evaluation is documented in subsection 3.5.2.2.2.1, item 3.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 045	BWR Only				
3.5-1, 046	Groups 1-3, 5-9: concrete: foundation; sub foundation	Reduction of foundation strength and cracking due to differential settlement and erosion of porous concrete sub foundation	Chapter XI.S6, “Structures Monitoring” If a de-watering system is relied upon for control of settlement, then the licensee is to ensure proper functioning of the de-watering system through the period of extended operation.	Yes, if a de-watering system is relied upon to control settlement (See SRP subsection 3.5.2.2.2.1.3)	Not applicable. Group 2 and 9 structures are not present at CPNPP. As described for item 3.5-1, 044 above, CPNPP does not rely upon a de-watering system to control settlement. In addition, structures are not founded on porous concrete foundations or sub foundations. Further evaluation is documented in subsection 3.5.2.2.2.1, item 3.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 047	Groups 1-5, 7-9: concrete (inaccessible): exterior above- and below-grade; foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See SRP subsection 3.5.2.2.2.1.4)	Consistent with the OE reflected in SLR-ISG-2021-03-STRUCTURES, a plant-specific AMP is not required for inaccessible concrete areas of Group 1, and 3 structures with foundations exposed to groundwater. Group 2 and 9 structures are not present at CPNPP. For LR, groundwater (other than seepage from the surface) is considered to be flowing water where leaching or carbonation could occur. The Structures Monitoring (B.2.3.34) AMP includes opportunistic inspection of inaccessible concrete surfaces, when excavated for other reasons, and will include evaluation of impact to inaccessible areas if leaching or carbonation is observed in accessible areas. Further evaluation is documented in subsection 3.5.2.2.2.1, item 4.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 048	Groups 1-5: concrete: all	Reduction of strength and modulus due to elevated temperature (>150°F general; >200°F local)	A plant-specific aging management program is to be evaluated.	Yes, if temperature limits are exceeded (See SRP subsection 3.5.2.2.2.2)	Not Applicable. Group 2 structures are not present at CPNPP. A plant-specific AMP is not required. Reduction of strength and modulus are not aging effects requiring management at CPNPP. CPNPP Group 1, 3, and 5 structures are not subject to general area temperatures greater than 150°F or local concrete temperatures greater than 200°F. Group 4 structures inside Containment (i.e., PSW) are addressed with item 3.5-1, 003. Further evaluation is documented in subsection 3.5.2.2.2.2.
3.5-1, 049	Groups 6 - concrete (inaccessible): exterior above- and below-grade; foundation; interior slab	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Further evaluation is required for plants that are located in moderate to severe weathering conditions (weathering index >100 day-inch/yr.) (NUREG-1557)	Yes, for plants located in moderate to severe weathering conditions (See SRP subsection 3.5.2.2.2.3.1)	Not applicable. CPNPP is located in a moderate weathering region with SWIS concrete that meets the air-entrainment and water-cement-ratio of ACI 318-71. The Texas climate is too warm to allow the development of significant ice on any lake. As such, loss of material and cracking due to freeze-thaw of SWIS concrete are not expected to occur. Further evaluation is documented in subsection 3.5.2.2.2.3, item 1.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 050	Groups 6: concrete (inaccessible): all	Cracking due to expansion from reaction with aggregates	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if concrete is not constructed as stated (See SRP subsection 3.5.2.2.2.3.2)	Consistent with the OE reflected in SLR-ISG-2021-03-STRUCTURES a plant-specific AMP is not required for the inaccessible areas of the CPNPP SWIS structure. Fine and coarse aggregates conform to ASTM C33. Petrographic examinations of aggregates were performed in accordance with ASTM C295 and ASTM C289. In addition, SWIS concrete SWIS is constructed in accordance with ACI 318. The Structures Monitoring (B.2.3.34) AMP is credited with managing cracking in inaccessible areas of the SWIS structure based on conditions in accessible areas. Further evaluation is documented in subsection 3.5.2.2.2.3, Item 2.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 051	Groups 6 - concrete (inaccessible): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Further evaluation is required to determine if a plant-specific aging management program is needed.	Yes, if leaching is observed in accessible areas that impact intended function (See SRP subsection 3.5.2.2.2.3.3)	Consistent with the OE reflected in SLR-ISG-2021-03-STRUCTURES, a plant-specific AMP is not required for the inaccessible areas of the CPNPP SWIS (Group 6) structure. The Structures Monitoring (B.2.3.34) AMP will be credited to manage increase in porosity and permeability and loss of strength of inaccessible concrete surfaces of the SWIS (intake bay) exposed to a flowing water environment (squaw creek reservoir water or groundwater), based on the conditions in accessible areas. In addition, accessible areas of the SWIS exposed to water - flowing are addressed in item 3.5-1, 061. Further evaluation is documented in subsection 3.5.2.2.2.3, item 3.
3.5-1, 052	Groups 7, 8 - steel components: tank liner	Cracking due to stress corrosion cracking; Loss of material due to pitting and crevice corrosion	A plant-specific aging management program is to be evaluated.	Yes, plant-specific (See SRP subsection 3.5.2.2.2.4)	Not applicable. Group 7 tanks at CPNPP are missile-protected concrete tanks with stainless steel liners. The concrete forms a tight seal with the liner and the configuration, with a concrete roof, precludes precipitation/rain (standing water) from getting between the concrete and liner. The FWSTs (Group 8 structures) are steel, addressed in item 3.3-1, 067 and managed, including the interface with the tank foundation, by the Fire Water System (B.2.3.16) AMP. Further evaluation is documented in subsection 3.5.2.2.2.4.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 053	Support members; welds; bolted connections; support anchorage to building structure	Cumulative fatigue damage due to cyclic loading (Only if CLB fatigue analysis exists)	Yes, TLAA	Yes, TLAA (See SRP subsection 3.5.2.2.2.5)	Not applicable. CLB fatigue analyses do not exist for support members, bolted connections; and anchorage to building structure. Containment liner and penetration fatigue is addressed in item 3.5-1, 009. Crane/hoist load cycle limits are addressed with item 3.3-1, 001. Further evaluation is documented in Section 3.5.2.2.2.5.
3.5-1, 054	All groups except 6: concrete (accessible): all	Cracking due to expansion from reaction with aggregates	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801 for Group 1, 3, 4, 5, and 7 structures, as well as accessible areas of the SWIS (Group 6 structure) that are above-grade/water-line. Group 2, and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP is credited with managing cracking due to expansion from reaction with aggregates.
3.5-1, 055	Building concrete at locations of expansion and grouted anchors; grout pads for support base plates	Reduction in concrete anchor capacity due to local concrete degradation/ service-induced cracking or other concrete aging mechanisms	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be credited with managing reduction in concrete anchor capacity for component supports and building framing exposed to air – indoor uncontrolled and air – outdoor environments.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 056	Concrete: exterior above - and below - grade: foundation: interior slab	Loss of material due to abrasion: cavitation	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP will be used to manage loss of material for exterior above grade and below-grade concrete exposed to flowing water.
3.5-1, 057	Constant and variable load spring hangers; guides; stops	Loss of mechanical function due to corrosion, distortion, dirt, overload, fatigue due to vibratory and cyclic thermal loads	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with exception to NUREG-1801. The ASME Section XI, Subsection IWF (B.2.3.31) AMP will be credited with managing loss of mechanical function for the passive portions of constant and variable load hangers of ASME Class 1, 2 and 3 piping systems exposed to an air – indoor uncontrolled environment. The ASME Section XI, Subsection IWF (B.2.3.31) AMP includes an exception.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 058	Earthen water-control structures: dams; embankments; reservoirs; channels; canals and ponds	Loss of material; loss of form due to erosion, settlement, sedimentation, frost action, waves, currents, surface runoff, seepage	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP will be used to manage loss of material or loss of form of the SSI and Dam including the spillway.
3.5-1, 059	Group 6: concrete (accessible): all	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP will be used to manage cracking, loss of bond, and loss of material of the accessible above-grade, below-grade, and interior concrete in the SWIS.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 060	Group 6: concrete (accessible): exterior above- and below-grade; foundation	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Not applicable. Loss of material and or cracking due to freeze and thaw is not applicable as the structures are located in a region where weathering conditions are considered moderate, as shown in ASTM C33-90, Figure 1. As described in Section 3.5.2.2.2.3, item 1, the Texas climate is too warm to allow the development of significant ice on any lake.
3.5-1, 061	Group 6: concrete (accessible): exterior above- and below-grade; foundation; interior slab	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP will be used to manage increase in porosity and permeability and loss of strength of the accessible above-grade concrete in SWIS components exposed to a flowing water environment.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 062	Group 6: Wooden Piles; sheeting	Loss of material; change in material properties due to weathering, chemical degradation, and insect infestation repeated wetting and drying, fungal decay	Chapter XI.S7, “Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants” or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Not applicable. No wooden piles or sheeting are used for any structure at CPNPP.
3.5-1, 063	Groups 1-3, 5, 7-9: concrete (accessible): exterior above - and below-grade foundation	Increase in porosity and permeability; loss of strength due to leaching of calcium hydroxide and carbonation	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP will be used to manage increase in porosity and permeability and loss of strength for accessible exterior concrete in Group 1, 3, 5 and 7 structures exposed to flowing water in the form of heavy drainage of rainwater.
3.5-1, 064	Groups 1-3, 5, 7-9: concrete (accessible): exterior above - and below-grade foundation	Loss of Material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S6, “Structures Monitoring”	No	Not applicable. Group 2 and 9 structures are not present at CPNPP. CPNPP is located in a moderate weathering region with concrete, for group 1, 3, 5 and 7 structures, that meet the air-entrainment and water-cement-ratio of ACI 318-71.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 065	Groups 1-3, 5, 7-9: concrete (inaccessible): below-grade exterior; foundation, Groups 1-3, 5, 7-9: concrete (accessible): below-grade exterior; foundation, Groups 6: concrete (inaccessible): all	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP will be used to manage cracking, loss of bond, and loss of material of inaccessible concrete in Groups 1, 3 and 6 structures exposed to a groundwater/soil environment. Group 5, and 7 structures, as well as certain Group 3 structures are founded above the water-table.
3.5-1, 066	Groups 1-5, 7, 9: concrete (accessible): interior and above-grade exterior	Cracking; loss of bond; and loss of material (spalling, scaling) due to corrosion of embedded steel	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP will be used to manage cracking, loss of bond, and loss of material of accessible concrete in Groups 1, 3-7 structures exposed to air indoor, and air outdoor environments. The Structures Monitoring (B.2.3.34) AMP also manages loss of bond and loss of material due to corrosion of masonry wall restraints, and reinforcements.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 067	Groups 1-5, 7, 9: Concrete: Interior; above-grade exterior, Groups 1-3, 5, 7-9 - concrete (inaccessible): below-grade exterior; foundation, Group 6: concrete (inaccessible): all	Increase in porosity and permeability; cracking; loss of material (spalling, scaling) due to aggressive chemical attack	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. Group 2 and 9 structures are not present at CPNPP. The Structures Monitoring (B.2.3.34) AMP will be used to manage increase in porosity and permeability, cracking, and loss of material of inaccessible concrete in Groups 1, 3 through 7 structures.
3.5-1, 068	High-strength structural bolting	Cracking due to stress corrosion cracking	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Not applicable. Bolting for ASME Class 1, 2, 3 and MC component supports, including moment restraints, do not have a measured yield strength > 150 ksi.
3.5-1, 069	High-strength structural bolting	Cracking due to stress corrosion cracking	Chapter XI.S6, "Structures Monitoring“ Note: ASTM A 325, F 1852, and ASTM A 490 bolts used in civil structures have not shown to be prone to SCC. SCC potential need not be evaluated for these bolts.	No	Not applicable. There are no structural bolts at CPNPP with a measured yield strength > 150 ksi. Also, the Structures Monitoring (B.2.3.34) AMP includes storage recommendations and prescription against the use of molybdenum disulfide or similar lubricants.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 070	Masonry walls: all	Cracking due to restraint shrinkage, creep, and aggressive environment	Chapter XI.S5, "Masonry Walls"	No	Consistent with NUREG-1801. The Masonry Walls (B.2.3.33) AMP will be used to manage cracking of masonry walls exposed to indoor air and outdoor air. As described in Table 3.5.2-15, some masonry walls and block openings include fire barriers and the Masonry Walls (B.2.3.33) AMP credits and communicates with the Fire Protection (B.2.3.15) AMP.
3.5-1, 071	Masonry walls: all	Loss of material (spalling, scaling) and cracking due to freeze-thaw	Chapter XI.S5, "Masonry Walls"	No	Not applicable. Freeze-thaw is not an applicable aging mechanism for masonry walls, or other structures, in the moderate North Central Texas environment of CPNPP, as described further in Section 3.5.2.2.2.1, item 1.
3.5-1, 072	Seals; gasket; moisture barriers (caulking, flashing, and other sealants)	Loss of sealing due to deterioration of seals, gaskets, and moisture barriers (caulking, flashing, and other sealants)	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP is credited with managing seals for watertight doors in the DGB, for manway openings of tanks, manhole covers and elastic joint filler in the yard, air-tight doors in the ECB (CRE), and tornado components in the AB, ECB, FB and SGBs as well as roofing membranes.
3.5-1, 073	Service Level I coatings	Loss of coating integrity due to blistering, cracking, flaking, peeling, or physical damage	Chapter XI.S8, "Protective Coating Monitoring and Maintenance"	No	Not used. Aging effects for Service Level 1 coatings are managed by the Protective Coating Monitoring and Maintenance (B.2.3.36) AMP as addressed under item 3.5-1, 034.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 074	Sliding support bearings; sliding support surfaces	Loss of mechanical function due to corrosion, distortion, dirt, debris, overload, wear	Chapter XI.S6, "Structures Monitoring"	No	Not used. Sliding surfaces are addressed for ASME Class I components in item 3.5-1, 075 below.
3.5-1, 075	Sliding surfaces	Loss of mechanical function due to corrosion, distortion, dirt, debris, overload, wear	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with exception to NUREG-1801. Loss of mechanical function due to corrosion, distortion, dirt, debris, overload, and wear is an applicable aging effect and mechanism for the Lubrite® blocks used on sliding surfaces for the RCS equipment supports Loss of mechanical function for these sliding surfaces will be managed by the ASME Section XI Subsection IWF AMP, which includes an exception.
3.5-1, 076	Sliding surfaces: radial beam seats in BWR drywell	Loss of mechanical function due to corrosion, distortion, dirt, overload, wear	Chapter XI.S6, "Structures Monitoring"	No	Not used. Sliding surfaces are addressed for ASME Class I components in item 3.5-1, 075 above.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 077	Steel components: all structural steel	Loss of Material due to corrosion	Chapter XI.S6, “Structures Monitoring” If protective coatings are relied upon to manage the effects of aging, the structures monitoring program is to include provisions to address protective coating monitoring and maintenance.	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of material of miscellaneous structural steel components exposed to indoor air, and steel and galvanized steel exposed to outdoor air. Protective coatings are not relied upon to manage the effects of aging of miscellaneous structural steel components at CPNPP.
3.5-1, 078	Steel components: fuel pool liner	Cracking due to stress corrosion cracking; Loss of material due to pitting and crevice corrosion	Chapter XI.M2, “Water Chemistry,” and Monitoring of the spent fuel pool water level in accordance with technical specifications and leakage from the leak chase channels	No, unless leakages have been detected through the SFP liner that cannot be accounted for from the leak chase channels	Consistent with NUREG-1801. The Water Chemistry (B.2.3.2) AMP is credited to manage loss of material and cracking of the stainless steel SFP liner and gate and refueling canal liner. The SFP water level is monitored in accordance with TSs. Monitoring of leak chase channels is performed as part of the Structures Monitoring (B.2.3.34) AMP. Fuel transfer tube and supports, fuel transfer upender, refueling canal liner and reactor vessel permanent cavity seal ring inside Containment are included, with the effectiveness of the Water Chemistry (B.2.3.2) AMP verified by the One-Time Inspection (B.2.3.19) AMP. A plant-specific note is used for the non-spent fuel components.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 079	Steel components: piles	Loss of material due to corrosion	Chapter XI.S6, "Structures Monitoring"	No	Not Applicable. CPNPP structures are not supported on pile foundations.
3.5-1, 080	Structural bolting	Loss of material due to general, pitting and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of material of steel structural bolting exposed to indoor air In addition, as listed in Table 3.5.2-14, the Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.3.13) AMP will be credited with managing loss of material for crane/hoist bolting exposed to indoor air.
3.5-1, 081	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with exception to NUREG-1801. The ASME Section XI, Subsection IWF (B.2.3.31) AMP will be used to manage loss of material of steel structural bolting associated with supports for ASME Class 1, 2, 3 piping and components. The ASME Section XI, Subsection IWF (B.2.3.31) AMP includes an exception.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 082	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S6, structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of material of steel and galvanized steel structural bolting exposed to outdoor air. In addition, as listed in Table 3.5.2-14, the Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.3.13) AMP will be credited with managing loss of material for crane/hoist bolting exposed to outdoor air.
3.5-1, 083	Structural bolting	Loss of material due to general, pitting, and crevice corrosion	Chapter XI.S7, "Regulatory Guide 1.127, Inspection of Water- Control Structures Associated with Nuclear Power Plants" or the FERC/US Army Corp of Engineers dam inspections and maintenance programs.	No	Consistent with NUREG-1801. The RG 1.127, Inspection of Water-Control Structures Associated with Nuclear Power Plants (B.2.3.35) AMP will be used to manage loss of material of steel structural bolting and miscellaneous structural components associated with Group 6 structures in outdoor air and raw water environments.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 084	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," and Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Consistent with exception to NUREG-1801. As listed in Table 3.5.2-13, loss of material for stainless steel bolting associated with ASME Class 2, 3 piping exposed to treated borated water in the fuel transfer canal/spent fuel pool will be managed by the Water Chemistry (B.2.3.2) AMP and ASME Section XI, Subsection IWF (B.2.3.31) AMP, both of which include exceptions. A generic Note B is used. As listed in Table 3.5.2-1, loss of material for stainless steel fuel transfer tube (containment closure) bolting and structural bolting associated with supports for ASME Class 2/MC components in the refueling cavity will be managed by the Water Chemistry (B.2.3.2) AMP, which includes an exception, and the ASME Section XI, Subsection IWE (B.2.3.29) AMP. A generic note E and plant-specific notes are used.
3.5-1, 085	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.M2, "Water Chemistry," for BWR water, and Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Not used. Loss of material for structural bolting exposed to treated borated water in the refueling cavity/spent fuel pool is addressed in item 3.5-1, 084.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 086	Structural bolting	Loss of material due to pitting and crevice corrosion	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with exception to NUREG-1801. The ASME Section XI, Subsection IWF (B.2.3.31) AMP will be used to manage loss of material of structural bolting associated with supports for ASME Class 3 piping and components exposed to outdoor air. The ASME Section XI, Subsection IWF (B.2.3.31) AMP includes an exception.
3.5-1, 087	Structural bolting	Loss of preload due to self-loosening	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with exception to NUREG-1801. The ASME Section XI, Subsection IWF (B.2.3.31) AMP will be used to manage loss of preload structural bolting associated with supports for ASME Class 1, 2, 3 piping and components. The ASME Section XI, Subsection IWF (B.2.3.31) AMP includes an exception.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 088	Structural bolting	Loss of Preload	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of preload of the steel, galvanized steel, and stainless steel structural bolting in any environment. Loss of preload for bolting associated with supports for ASME Class 1, 2 and 3 piping and components is addressed in item 3.5-1, 087 above. In addition, as listed in Table 3.5.2-14, the Inspection of Overhead Heavy Load and Light Load (Related to Refueling) Handling Systems (B.2.3.13) AMP will be credited with managing crane/hoist bolting exposed to outdoor air.
3.5-1, 089	Support members; welds; bolted connections; support anchorage to building	Loss of material due to boric acid corrosion	Chapter XI.M10, “Boric Acid Corrosion”	No	Consistent with NUREG-1801. The Boric Acid Corrosion (B.2.3.4) AMP will be used to manage loss of material due to BAC of aluminum, steel, and galvanized steel miscellaneous structural components, support members, welds, bolted connections, and support anchorage to building structure for piping and component supports exposed to air with potential borated water leakage. Air locks and accessories, control rod drive missile shield, leak channel screw caps, liner plate, and penetration assemblies inside Containment are also included, as are cabinets, and other structural components and insulation jacketing potentially exposed to air with borated water leakage.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components					
Item Number	**Component**	**Aging Effect Requiring Management**	**Aging Management Program**	**Further Evaluation Recommended**	**Discussion**
3.5-1, 090	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general (steel only), pitting, and crevice corrosion	Chapter XI.M2, “Water Chemistry,” for BWR water, and Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with exception to NUREG-1801. The Water Chemistry (B.2.3.2) AMP and ASME Section XI, Subsection IWF (B.2.3.31) AMP will be used to manage loss of material for stainless steel ASME Class 2, 3 piping and component supports exposed to treated borated water in the SFP. The Water Chemistry (B.2.3.2) AMP and ASME Section XI, Subsection IWF (B.2.3.31) AMP each include an exception.
3.5-1, 091	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general and pitting corrosion	Chapter XI.S3, “ASME Section XI, Subsection IWF”	No	Consistent with exception to NUREG-1801. The ASME Section XI, Subsection IWF (B.2.3.31) AMP will be used to manage loss of material for steel supports, welds, bolted connections, support anchorage to building structure for ASME Class 1, 2, 3 piping and components. The ASME Section XI, Subsection IWF (B.2.3.31) AMP includes an exception.
3.5-1, 092	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to general and pitting corrosion	Chapter XI.S6, “Structures Monitoring”	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of material of steel (Non-ASME) support members, welds, and other structural components that are exposed to an air-indoor uncontrolled and air-outdoor environment.

Table 3.5-1 Summary of Aging Management Programs for Containment Building and Internal Structural Components

Item Number	Component	Aging Effect Requiring Management	Aging Management Program	Further Evaluation Recommended	Discussion
3.5-1, 093	Support members; welds; bolted connections; support anchorage to building structure	Loss of material due to pitting and crevice corrosion	Chapter XI.S6, "Structures Monitoring"	No	Consistent with NUREG-1801. The Structures Monitoring (B.2.3.34) AMP will be used to manage loss of material of aluminum, stainless steel, and galvanized steel (Non-ASME) support members, welds, bird screens, cabinets, metal siding, tornado dampers and panels, transmission towers and other structural components that are exposed to an air-outdoor environment. For stainless steel and aluminum, the focus is on areas where water could pool or get within insulation jacketing.
3.5-1, 094	Vibration isolation elements	Reduction or loss of isolation function due to radiation hardening, temperature, humidity, sustained vibratory loading	Chapter XI.S3, "ASME Section XI, Subsection IWF"	No	Not applicable. The CPNPP supports for ASME Class 1, 2 and 3 piping and components do not include vibration isolation elements.
3.5-1, 095	Aluminum, galvanized steel and stainless steel support members; welds; bolted connections; support anchorage to building structure exposed to Air – indoor, uncontrolled	None	None	NA – No AEM or AMP	Consistent with NUREG-1801 for support members, bird screens, cabinets, metal siding and other structural components that are not susceptible to frequent or prolonged water pooling.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

H. Neither the component nor the material and environment combination are evaluated in NUREG-1801.

Plant-Specific Notes

1. Components are ASME Class 2 and MC.

2. OE reflected in SLR-ISG-2021-03-STRUCTURES indicates that the ASME Section XI, Subsection IWL (B.2.3.30) AMP and/or Structures Monitoring (B.2.3.34) AMP may be credited in place of a plant-specific program.

3. Groundwater below the existing water table (reactor vessel cavity pit protrusion through bottom of the foundation mat) and heavy rainwater are considered as water – flowing. However, leaching has not been observed in accessible exterior Containment Building locations.

4. The outer cover for the emergency hatch is not a pressure boundary component and will be managed by the Structures Monitoring (B.2.3.34) AMP instead of the ASME Section XI, Subsection IWE (B.2.3.29) AMP.

5. Will be managed by the Water Chemistry (B.2.3.2) and One-Time Inspection (B.2.3.19) AMP in accordance with LR-ISG-2011-01: Aging Management of Stainless Steel Structures and Components in Treated Borated Water, Revision 1.

6. The recirculation sump effluent guard pipe is not considered part of the barrier between Containment and the external environment and is not tested at Containment design condition.

7. Stainless steel metal reflective insulation is used in Type I, II, and III high temperature Containment penetrations and in the primary shield RCS penetrations as thermal insulation.

8. Calcium silicate is used in Type IV Containment penetrations as thermal insulation.

9. Leak chase channels are inaccessible following construction, with the exception of threaded screw caps in depressions in the operating floor.

10. Stainless steel closure bolting associated with the fuel transfer tube and fuel transfer tube supports inside Containment (refueling canal) are periodically exposed to treated borated water and will be managed by the Water Chemistry (B.2.3.2) AMP and ASME Section XI, Subsection IWE (B.2.3.29) AMP.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Locations with prolonged or frequent water pooling that may contain aggressive chemicals or absorb into the concrete, and corrode embedded steel, are most susceptible.

2. Bottom of the AB foundation is located above the water table such that groundwater is limited to absorbed surface water and perched water.

3. Rainwater, particularly periodic heavy north central Texas rains, is considered water-flowing.

4. Concrete aging effect conservatively applied to masonry walls.

5. Exterior walls adjacent to other Seismic Category 1 structures are inaccessible due to the elastic joint filler in the gap.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Locations with prolonged or frequent water pooling that may contain aggressive chemicals or absorb into the concrete, and corrode embedded steel, are the most susceptible.

2. Bottom of the DGB foundation is located above the water table such that groundwater is limited to absorbed surface water and perched water.

3. Rainwater, particularly periodic heavy north central Texas rains, is considered water-flowing.

4. At locations of frequent or prolonged water pooling, such as the lower portion of the watertight doors.

5. Masonry (bricks) and mortar between silencer and DGB roof.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Locations with prolonged or frequent water pooling that may contain aggressive chemicals or absorb into the concrete, and corrode embedded steel, are most susceptible.

2. Bottom of the ECB foundation is below the water table, with groundwater limited to absorbed surface water and perched water down to the water table.

3. Rainwater, particularly periodic heavy north central Texas rains, and groundwater below the water table are considered water-flowing.

4. Concrete aging effect conservatively applied to masonry walls.

5. Exterior walls adjacent to other Seismic Category 1 structures are inaccessible due to the elastic joint filler in the gap.

6. Aging effect of cracking due to cracking, loss of bond and loss of material in concrete below grade exterior (inaccessible) will be evaluated and monitored under the Structures Monitoring (B.2.3.34) AMP.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

B. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

D. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP takes some exceptions to NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Locations with prolonged or frequent water pooling that may contain aggressive chemicals or absorb into the concrete, and corrode embedded steel, are the most susceptible.

2. Bottom of the FB foundation is located above the water table such that groundwater is limited to absorbed surface water and perched water.

3. Rainwater, particularly periodic heavy north central Texas rains, is considered water-flowing.

4. Concrete aging effect conservatively applied to masonry walls.

5. SFP Leak chase channels are monitored as part of the Structures Monitoring (B.2.3.34) AMP.

6. SFP bulk temperature is maintained < 150°F.

7. Includes the exterior of the service water tunnel that passes beneath the FB.

8. Coated steel plate is installed at the wall penetration as an exterior wall sleeve/collar for pipes entering the building/structure and will be monitored as part of the Structures Monitoring (B.2.3.34) AMP instead of the Buried and Underground Piping and Tanks (B.2.3.27) AMP.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

C. Component is different, but consistent with NUREG-1801 item for material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

E. Consistent with NUREG-1801 item for material, environment, and aging effect, but a different AMP is credited or NUREG-1801 identifies a plant-specific AMP.

Plant-Specific Notes

1. Locations with prolonged or frequent water pooling that may contain aggressive chemicals or absorb into the concrete, and corrode embedded steel, are most susceptible.

2. Bottom of the SGB foundation for each unit is below the water table, with groundwater limited to absorbed surface water and perched water down to the water table.

3. Rainwater, particularly periodic heavy north central Texas rains, and groundwater below the water table are considered water-flowing.

4. Concrete aging effect conservatively applied to masonry walls.

5. Exterior walls adjacent to other Seismic Category 1 structures are inaccessible due to the elastic joint filler in the gap.

Generic Notes

A. Consistent with NUREG-1801 item for component, material, environment, and aging effect. AMP is consistent with NUREG-1801 AMP.

G. Environment not in NUREG-1801 for this component and material.

Plant-Specific Notes

1. Consistent with the OE reflected in NUREG-2192 (III.A6.T-22 / 3.5-1, 058), the Air -outdoor environment (portions of the SSI, Dam and Spillway) above the water-line are also included.
